The death is announced, at the age of 86, at Pau, of Dr. DOLERIS, who in 1924 was President of the French Academy of Medicine. His interests were wide; he made his mark in medicine as a gynaecologist, but he also played a distinguished part in scientific agriculture, and he represented his constituency in the French Parliament between 1921 and 1924. The late Dr. LE TELLIER was at one time President of the Ligue Française Homéopathique, and in 1933 he was the President of the International Homoeopathic League.

The following well-known foreign medical men have recently died: Dr. RICHARD HERMANN JAFFE, an eminent pathologist and bacteriologist of Vienna, aged 50; Geh. San. Rat Dr. STODER, for many years leader of the Bavarian medical profession; Dr. OTTO KREN, a distinguished Viennese dermatologist; Dr. M. BOGUNOVIC, professor of gynaecology at Belgrade; Dr. LÉON BELLIN, the Paris oto-rhino-laryngologist, aged 64; Dr. RAYMOND SABOURAUD, the eminent Paris dermatologist and great authority on parasitic diseases of the skin, especially ringworm, aged 73; and Professor WERNER KÖRTE, permanent secretary of the German Society of Surgery and an authority on the surgery of the pancreas and bile ducts.

Mr. HARTLAND S. WRIGHT, who died on February 16 in his ninetyeth year, was actively associated with the business of John Wright and Sons Ltd., the Bristol printers and publishers, for over seventy years, and had been chairman since the incorporation of the company.

Universities and Colleges

UNIVERSITY OF OXFORD

In Congregation on February 22 the Regius Professor of Medicine, Sir Farquhar Buzzard, proposed that the degree of Doctor of Medicine be conferred by decree of the House upon the following four newly appointed Professors:

H. W. B. Cairns, Fellow of Balliol, Nuffield Professor of Surgery.

R. R. Macintosh, Fellow of Pembroke, Nuffield Professor of Anaesthetics.

J. Chassar Moir, Fellow of Oriel, Nuffield Professor of Obstetrics and Gynaecology.

J. A. Gunn, Fellow of Balliol, Nuffield Professor of Therapeutics.

The House approved the conferment of these degrees.

UNIVERSITY OF CAMBRIDGE

At a congregation held on February 19 the following medical degrees were conferred:

M.B., B.Chir.—S. B. Darbishire, *E. B. Hacking, *M. Williams, L. H. Cane, H. G. W. Hoare, J. M. G. Wilson, G. Sheers, R. McK. Miller.

M.B.—S. A. Probert, *G. L. Foss, R. E. Rodgers.

* By proxy.

The Professor of Physiology announces that a public lecture will be given in the Lecture Theatre of the Physiological Laboratory on Thursday, March 10, at 5 p.m., by Professor A. P. H. A. De Kleijn of the University of Amsterdam. The subject of the lecture is "Some Remarks on Vestibular Physiology."

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE

A special University Lecture in biochemistry on "The Role of Dicarboxylic Acids in Metabolism" will be given at University College, Gower Street, W.C., by Dr. P. E. Verkade, professor of chemistry and chemical technology in the Nederlandsche Handels-Hoogeschool, Rotterdam, on Thursday, March 10, at 5 p.m. The lecture, which will be delivered in English, has been arranged under a scheme for the exchange of lecturers between England and Holland. It is addressed to students of the University and to others interested in the subject, and will be illustrated with lantern slides. Admission is free, without ticket.

UNIVERSITY OF LEEDS

Dr. M. J. McGrath, medical superintendent of the West Riding Mental Hospital, has been appointed lecturer in mental diseases.

UNIVERSITY OF EDINBURGH

The Senatus Academicus, on the recommendation of the Faculty of Medicine, has awarded the Cameron Prize for 1936 to Karl Landsteiner, M.D., member of the Rockefeller Institute for Medical Research, New York; and the Straits Settlements Gold Medal to Thottakat Bhaskara Menon, M.D., M.R.C.P.

The Services

ARMY MEDICAL SERVICES

The War Office announced on February 21 that the King has approved of the following promotion and appointments:

Colonel F. Casement, D.S.O., late R.A.M.C., Deputy Director-General, Army Medical Services, at the War Office, to be promoted to the rank of Major-General and to be appointed Deputy Director-General of Medical Services, Southern Command, with effect from April 15, in succession to Major-General O. Ievers, C.B., D.S.O., K.H.S., late R.A.M.C., who will vacate the appointment on completion of four years' service as Major-General.

Colonel O. W. McSheehy, D.S.O., O.B.E., at present Assistant Director of Medical Services, Home Counties Area (West) at Woolwich, to be Deputy Director-General, Army Medical Services, in succession to Colonel Casement.

DEATHS IN THE SERVICES

Squadron Leader RONALD ELTRINGHAM ALDERSON, R.A.F.M.S., was killed on February 18 near Athlit, south of Haifa, Palestine, when the taxi in which he was travelling was fired on by a party of bandits, a lady travelling in the same car being also dangerously wounded. He was educated at Durham University, where he gained a University Scholarship in 1922, the Goyder and Philipson scholarships in 1927, and graduated M.B., B.S. in 1927. After filling the posts of house-surgeon at the Royal Victoria Infirmary, Newcastle-upon-Tyne, and medical officer of the Ministry of Pensions Hospital at Newcastle, he entered the Royal Air Force, and at the time of his death was serving in the R.A.F. General Hospital for Palestine and Transjordan, to which he was posted as squadron leader on March 14, 1927.

Lieutenant-Colonel ALFRED THOMAS IRVINE LILLY, R.A.M.C. (ret.), died at Ealing on February 13, aged 76. He was born at Hingoli in the Deccan, India, on September 8, 1861, was educated at St. George's Hospital, and took the M.R.C.S., L.R.C.P. in 1884. He entered the Army as surgeon on January 31, 1885, became lieutenant-colonel after twenty years' service, and retired on December 28, 1917. He served in the South African War from 1899 to 1902, taking part in the operation in the Orange Free State, the Transvaal, and Cape Colony, including the actions at Belfast and Lydenburg, and received the Queen's medal with three clasps and the King's medal with two clasps. He also served in the war of 1914-18.

of those who take the conjoint examination *could* pass the M.B., B.S., why do they not do so? Is it not that they embarked upon medicine without a matriculation standard of general education, or else that they failed to stay the course?

It was somewhat disconcerting to read of the shortcomings of graduated assistants. From the letter in question one gathers that they are completely incapable. I suggest that the young assistant fresh from a house job is often better versed in modern technique than his employer. For example, he has usually been dealing with more cases daily that require minor surgical procedure than the general practitioner deals with in a month. In fact he often leaves his hospital post with the impression, judging from cases he has seen in the casualty department, that many practitioners are either incapable or lazy. Incidentally, the practitioner should surely show some discrimination when engaging an assistant.—I am, etc.,

BASIL S. KENT, M.B., B.S.Lond.

Crouch End, N.8, Feb. 8.

Obituary

HERBERT LUND, M.B., F.R.C.S.

We regret to announce the death on February 18, in his eightieth year, of Mr. Herbert Lund of Manchester.

The son of Edward Lund, F.R.C.S., one-time professor of surgery in the Owens' College, Manchester, he was born in 1858. Edward Lund moved from Surrey to Manchester and became a leader in the surgical life of the town, and continued in activity for many years. He introduced Listerism into the Royal Infirmary when others remained aloof and scornful of its reputed virtues. Herbert Lund took his B.A. in the Natural Sciences Tripos at Cambridge in 1881 and the M.B., B.Ch. five years later. In the meantime he qualified from Guy's Hospital with the M.R.C.S. in 1885, and after holding resident posts in the hospital he settled in Manchester. The F.R.C.S. was received in 1887, and in 1889 he was appointed honorary assistant surgeon to Salford Royal Hospital. He continued in active work there until his sixtieth year in 1918, when by regulation of the hospital he joined its consulting staff. In the war of 1914-18 he was attached to the 2nd Western General Hospital with its headquarters in Manchester, and later was a referee on the War Pensions Board in Salford. Useful service was done for many years as medical referee to Lancashire County Courts under the Workmen's Compensation Act. Although he kept the name of Lund alive in Manchester and Salford, he was of a somewhat retiring nature and did not take such a leading part in its consultant and scientific life as his father, who was twice president of the Medical Society (1863 and 1881); secretary from 1850 to 1853, and one of its most useful members.

Herbert Lund published some papers on the surgical treatment of diseases of the urinary organs. He was a keen and extensive stamp collector and a member of the local Philatelic Society. He had been a member of the British Medical Association for twenty-eight years, and when the Association held its Annual Meeting at Manchester in 1902 he acted as secretary of the Section of Surgery.

We regret to record the death on February 10 of Dr. JOHN COURTENAY MACWATTERS at his residence in Almondsbury, near Bristol, at the age of 64. He entered the Bristol Medical School in 1891, and obtained the diplomas M.R.C.S., L.R.C.P. five years later. In 1897 he was appointed to the newly created post of resident obstetric

officer to the Bristol Royal Infirmary, where he was also house-physician and clinical assistant. About 1901 he removed to Almondsbury, where he had lived ever since, taking a long and very active interest in Almondsbury Memorial Hospital, of which he was medical officer. He built up a large general practice and was very popular throughout the district. At one time he devoted himself to the possibilities of therapeutic immunization, contributing articles on this subject to the *British Medical Journal* and other periodicals. An article by him on the vaccine treatment of pyorrhoea appeared in the *Journal of the British Dental Association* in 1913. Dr. MacWatters had been a member of the British Medical Association since 1899.

Mr. ERNEST CHARLES ARNOLD, F.R.C.S., who died on February 10 at his residence in Westbourne Road, Forest Hill, at the age of 77, had been a member of the British Medical Association for over forty years. He was a medical student at St. George's Hospital, graduating M.B.Durham in 1886 and obtaining the diploma F.R.C.S. in 1888. He had studied also in Vienna and Berlin, his special interest being ophthalmology. At St. George's Hospital he held the posts of senior assistant demonstrator of anatomy, ophthalmic assistant, and house-surgeon. Other appointments held by him earlier in life were those of out-patient officer to the Royal London Ophthalmic Hospital and refractionist to the Royal Westminster Ophthalmic Hospital. He was ophthalmic surgeon to the cottage hospital in Welwyn Garden City and ophthalmic medical officer for out-patients to Queen Mary's Hospital, Stratford. Mr. Arnold was for some time in the service of the London County Council as an ophthalmic officer. He was a member of the West Kent Medico-Chirurgical Society; and during the war held a commission as captain R.A.M.C.

Dr. FRANK PATTERSON, F.A.C.S., Leader of the Conservative Party in British Columbia and of the Opposition in the Legislature, died in Vancouver on February 11 at the age of 61. He graduated at McGill University in 1898, and subsequently specialized in bone diseases, becoming widely known for his work among crippled children. He held a commission during the war. He was a member of the Canadian Medical Association, the North Pacific Surgical Association, and was elected a Fellow of the American College of Surgeons. After a very full professional life Dr. Patterson turned his attention to politics, being elected party leader eighteen months ago and to the Legislature last year. His work as Leader of the Opposition during the last session was conducted under the great handicap of serious illness.

Dr. HENRY ANGUS, who was medical officer of health for Bingley, Yorks, for over thirty years before his retirement in 1933, died at his home on February 14, aged 74. A medical student of Aberdeen, who graduated M.B., C.M. in 1886 and M.D. in 1898, he played a large part in helping to raise the standard of health in the district which he served. He was closely connected with Bingley Hospital for many years, and during the war worked at Morton Banks War Hospital. Dr. Angus was a former president of the Bradford Medical Society, of which he had been a member for nearly fifty years, and was an honorary life member of the St. John Ambulance Association.

Mr. ROBERT MARSHAL GOING, F.R.C.S., late of Littlehampton, died at his residence in Tonbridge on February 14. He was the son of the late Archdeacon Going of Killaloe, and was born in 1867. He was educated at St. Columba's College, Trinity College, Dublin, and the London Hospital. Having taken the L.M. at the Rotunda Hospital in 1890, he graduated M.B., B.Ch., B.A.O. in 1891, obtained the diplomas M.R.C.S., L.R.C.P. in 1896, and proceeded F.R.C.S. in the next year. In 1891 he was

dents, but the Board of Control had answered inquiries from local authorities and medical superintendents in so far as it was competent for the board to advise.

Typhoid and Tinned Foodstuffs.—On February 15 Mr. BERNAYS informed Mr. Rhys Davies that in connexion with outbreaks of typhoid fever investigations had been made into the possibility of contamination from tinned foodstuffs. All articles of food and drink consumed by the patients during the material periods were considered. The Minister of Health was not aware that the source of infection in any outbreak of typhoid fever had been traced to the consumption of tinned foodstuffs.

Tyneside Health Services.—The Minister of Health has sent letters to the Northumberland County Council and the Newcastle City Council suggesting informal exploration by the two authorities of the possibility of co-ordinating public health medical services. The city council has agreed to appoint a committee to consider the matter, and the county council had the subject before them this week.

Employment of Water Engineer by Local Authorities.—On February 21 Sir KINGSLEY WOOD informed Mr. Rhys Davies that all local authorities with populations of 200,000 and over other than the Croydon Corporation had a water engineer who was employed solely for the purpose of supervising their water supply undertaking.

Pulmonary Disease among Coal Miners.—On February 22 Earl WINTERTON, replying to Mr. J. Griffiths, said that following the closure of the pit originally selected by the special committee of the Medical Research Council the investigation into chronic pulmonary disease among coal miners was transferred to the Ammanford Colliery, South Wales, early in December. Satisfactory progress was being made there, both in the medical and in the environmental inquiries. The work at this colliery would probably be completed about the end of March, after which some time would have to be given to a study of the information collected. It was proposed thereafter to extend the investigation to another anthracite colliery, but the selection of a pit would depend on the results of the work at present being done. It was not yet possible to indicate any date for the completion of the investigations as a whole.

Nutrition Investigation at Stockton.—Sir KINGSLEY WOOD, replying to a question put down by Captain Elliston on February 22, said the Stockton-on-Tees Town Council had informed him that in present circumstances it was not possible for them to release their medical officer of health, who was a full-time officer of the corporation, to undertake the proposed investigation by the Ministry into problems of nutrition. The investigation would entail about one day per fortnight for one year.

Notes in Brief

During 1937 the Minister of Health approved 4,235 orders for clearance of slum areas. The orders were made by 409 local authorities in England and Wales and affected 192,000 persons.

Patients discharged by the Board of Control from certified institutions under the Mental Deficiency Act, 1913, were: 152 in 1936 and 200 in 1937.

All local supervising authorities in the county of Devon have prepared proposals under the Midwives Act, 1936. The Minister of Health has no information of a shortage of certified midwives in that county.

Glasgow Corporation completed 1,841 houses in 1937 and 1,985 in 1936.

A memorandum for local authorities containing information relative to the Factories Act is in course of preparation.

In England and Wales approximately 1,000,000 persons remain to be rehoused from houses included in the slum clearance programmes of local authorities.

The latest figures of juveniles in attendance at the three junior instruction centres conducted by the Rhondda local

education authority who have been certified as in need of supplementary nourishment show an increase on earlier figures.

At the end of January 2,121 officers, nurses, and men were receiving hospital treatment for war disabilities.

On March 31, 1937, the latest date for which figures are available, 29,385 physically defective children and 13,815 mentally defective children were on the registers of certified special schools in England and Wales.

Sir Samuel Hoare states that under the silicosis schemes the medical board can, and often does, give a certificate where the silicosis is not the primary cause of death but is a secondary and accelerating cause.

The cost of the research work at present directed by the Industrial Health Research Board is approximately £9,500 yearly. The programme has not included any research into rheumatism.

SOCIETY OF APOTHECARIES' DINNER

The Society of Apothecaries of London held a Livery Dinner on February 22 at the Hall of the Society, the Master, Mr. Hugh Lett, being in the chair. After the loyal toasts had been honoured the health of the Society was proposed by Sir StClair Thomson, who introduced himself in the terms of the title of one of Priestley's plays—"I have been here before." The first occasion was in 1881, when, after an interview with the examiners at Apothecaries' Hall, he had sent off the following telegram: "Dearest Mother, I am licensed to kill." This, he said, launched him on fifty-seven years of happy work in the medical profession. As he was now enjoying *otium cum dignitate* he had avoided "mugging up" an impromptu speech. Sir StClair's discourse then centred upon a plaque of glazed pottery bearing the Arms of the Society, which he was about to present to it. After sketching the history of Lambeth pottery from the days of Charles I to George III he gave a racy account of the anatomy of heraldry, which he linked up with the perennial youth of the Society of Apothecaries.

In response the Master said that Sir StClair Thomson had long been known as "the honey-tongued Nestor" of our profession. In briefly recording recent events in the life of the Society he referred to the fact that during the past few months they had promoted to the Livery Mr. W. T. Withers, who had come to the Society as assistant bedel in 1887. It was not possible, Mr. Lett continued, to overstate the value Mr. Withers had been to the Society, and in welcoming him to the dinner he presented him with a memento from a past Master. He drew attention to the special lighting of the pictures "in the next room," and told the story of how Sir Joshua Reynolds had managed to get Hunter to sit for a portrait without a beard; the one with a beard was at Apothecaries' Hall and the one without at the Royal College of Surgeons. Mr. Hugh Lett also mentioned a tablet of Robert Harris, a Master of the Society in 1687, which had been discovered in Wisbech. Finally he thanked Sir StClair Thomson for the valuable plaque he had presented. The health of the guests was proposed by the Junior Warden, Mr. L. Vernon Cargill, who mentioned that both he and Sir StClair Thomson had been house-surgeons to Lister. In welcoming Dr. G. C. Anderson, the Secretary of the British Medical Association, he reminded those present that the Society of Apothecaries, together with the B.M.A., had formed the *Register of Medical Auxiliaries*.

Replying for the guests, Dr. Anderson returned thanks for the kindly hospitality they had all received. He recalled that in his student days he was taught that at times it was necessary to administer a corrective, and lately it had been his task to consider what correctives should be administered as regards medicine to the public of this country through the Press. A doctor drunk in charge of a car was "news," as he always was when he got into trouble. They should try to make news of the more normal and pleasanter aspects of his professional life.

Medical Notes in Parliament

Both Houses of Parliament this week debated foreign policy on the resignation of Mr. Eden from the Secretaryship of State for Foreign Affairs.

In the House of Lords on February 17 the Divorce and Nullity (Scotland) Bill passed through committee. On February 22 in the same House the Population (Statistics) Bill and the Blind Persons Bill, which passed the Commons on February 17, were read a first time.

By 150 to 198 the House of Commons carried on February 16 a motion proposed by Mr. Leach which called for a committee to inquire into the practicability of granting a pension of 10s. weekly to spinsters at 55 years of age.

The National Health Insurance (Amendment) Bill was read a second time in the Commons on February 17. Sir Kingsley Wood explained that it was intended to preserve to certain persons in "family employment" the right to a free insurance period and the option of becoming voluntary contributors.

Dr. Haden Guest moved the second reading of the Bakehouses Bill in the House of Commons on February 18. The object of the Bill is to prohibit night work in bakehouses. He said the men worked in dust, high temperature, and glaring light which affected their eyesight. The Registrar-General reported that there was among bakers a high death rate from phthisis. The Bill was read a second time by 147 to 126.

A conference between dental practitioners and the Parliamentary Medical Committee was arranged for February 24.

Parliament and Rheumatic Disease

Fifteen members of Parliament accepted an invitation to attend a meeting convened by the Medical Committee of the House of Commons on February 17 to discuss the formation of a Parliamentary Group to assist the Empire Rheumatism Council. Sir Francis Fremantle presided. Lord HORDER said rheumatism cost this country £17,000,000 annually in wages and in sick pay paid by the approved societies alone. Medicine was greatly in arrears in an exact survey of the field and in assaying causative factors. To fill that gap in the national health defences the Empire Rheumatism Council came into being. The Council hoped to be able to say what was really the position in this country and in the Dominions. From the Falkland Isles, Fiji, Rhodesia, and elsewhere useful facts and suggestions had been received and research into this information was being instituted. Old fallacies were being exposed. Australia, for example, showed as much rheumatism despite its sunny and dry climate as did Great Britain. This confirmed the growing belief that the climatic factor in causation had been overestimated. Climatic and environmental factors were likely to prove determining rather than primary or essential. These essential causes so far eluded research, or perhaps did not so much elude as confuse. Enthusiasts and empirics attributed rheumatism to a focus of microbic infection, to defective nutrition, to climatic, to occupational, or to nervous factors, but the problem was more complex than that. Side by side with the double task of searching for causes and of segregating types of rheumatic diseases the Council proposed an inquiry into all accepted methods of treatment now followed. In this task the staff of the Ministry of Health was with them. Lord HORDER suggested that any member of either House who was willing to help the Council would be invited to join its ranks, and the Parliamentary Group would be asked to nominate

members to the key committees of the Council. They could give great practical help in educating the public and in enlisting the sympathy of the leaders of industry. The Council would also look to the Parliamentary Group for advice on all questions affecting legislation and public administration. Other speakers were Sir William Willcox, Dr. Mervyn Gordon, Dr. W. S. C. Copeman, and Sir Frank Fox.

Voluntary Patients in Mental Hospitals

Mrs. TATE asked on February 17 the number of voluntary patients applying for treatment at public mental hospitals in each year since the passing of the Mental Treatment Act, 1930, and the number of these patients who were subsequently certified. Sir KINGSLEY WOOD, in reply, furnished these statistics:

Year	Admissions	Subsequently Certified
1931	1,495	65
1932	2,295	108
1933	2,961	131
1934	4,078	129
1935	5,834	181
1936	6,904	177

Figures for 1937 are not yet available.

Price of Milk to Hospitals

On February 21 Mr. W. S. MORRISON, replying to Mr. C. Wilson and Mr. Boulton, said that the milk-in-schools scheme was initiated with a view to encouraging the milk-drinking habit in children. Different considerations applied to the question of the price paid for milk by hospitals. Mr. BOULTON asked if the Minister did not think that the hospitals were receiving somewhat exceptional treatment and if he would consider some other method. Mr. MORRISON replied that at present the hospitals were getting milk at wholesale rates. He did not see why producers of milk should supply milk below cost price any more than those who supplied bandages should do so. Replying to further questions, Mr. Morrison said he was not aware of the statement that had been published that the cost of milk to hospitals had now gone up by £400,000 a year. If there had been an increase in the cost of milk to hospitals it should be compared with the price charged at the time when the whole industry was in a state of collapse, and if it had not been for the action of the Milk Board there would have been a serious shortage of milk in this country.

Maternity Services in Scotland

In replying to Mr. Westwood on February 22 Mr. ELLIOT said that agreement had been reached with the Scottish Committee of the British Medical Association on the revised terms of remuneration which they were prepared to recommend for acceptance by members of the Association for medical services under the Maternity Services (Scotland) Act, 1937. It had been agreed that the basic fee should be 40s. per case for all attendances during pregnancy, labour, and the lying-in period, including ante-natal examinations and a post-natal examination. Insured women were entitled to certain ante-natal services under the national health insurance scheme, and accordingly it had been agreed that in these cases the basic fee should be 36s. The terms would be subject to review at the end of an experimental period of two years.

Replying to a further question by Mr. Westwood, Mr. Elliot said he understood that there would be some arrangement between the local authorities and the medical practitioners to give effect to the scheme he had outlined.

Mental Hospital Patients and Matrimonial Causes Act.—On February 15 Mr. SORENSEN asked the Minister of Health what advice had been given to medical superintendents of public mental hospitals respecting patients likely to be affected by proceedings under the Matrimonial Causes Act. Mr. BERNAYS replied that the matter had not been made the subject of a general communication to medical superintendents.

EPIDEMIOLOGICAL NOTES

Enteric Fever

One further case of typhoid fever in the Somerset outbreak was notified during last week, the number now being 40, while the addition of one fatal case brings the total number of deaths to 6.

Dysentery

Bacillary dysentery appears to be on the increase in England and Wales, the notifications for the week being 242 compared with 215 in the previous week. For London the figures are 91 and 50 respectively. The increase affected chiefly the home counties: there were notified in Middlesex 23 cases, in Essex 9, Kent 15, Surrey 11; in all areas the disease was widely scattered in both urban and rural districts. In London boroughs the figures were as follows: Wandsworth 35, Shoreditch 6, Kensington 5, Islington 5, and 4 each in Chelsea and Holborn.

Diphtheria

Notifications of diphtheria in England and Wales continue to drop, there being 1,738 for the week compared with 1,874 in the previous week; the London figures remained almost stationary. The deaths in England and Wales for the week have been 29, compared with 37 in the previous week, and 3 compared with 4 in the county of London. In Eire notifications rose from 58 to 78, while in Scotland and Northern Ireland they were practically the same. Diphtheria appears to have increased in incidence and severity in Leeds, in which town 37 cases were notified compared with 19 in the previous week; during this period there were 2 fatal cases, while in the previous week no deaths were reported. The incidence in the West Riding (Yorks) has declined slightly from 221 to 207, in Bradford from 30 to 13, and in Sheffield from 49 to 45.

Scarlet Fever

The incidence of scarlet fever in England and Wales has dropped during the week from 2,417 to 2,326, but is still greater than the median value for the last nine years—1,999. In London notifications have increased from 168 to 193, but the numbers remain well below the median value of 242.

Measles

During the week under review there were in England and Wales 40 deaths from measles, as compared with 27 in the previous week. The principal towns affected were Greater London 7 (7), administrative county of London 6 (3), Liverpool 15 (6), Manchester 6 (5), Bristol 2 (1). The figures in parentheses denote the deaths in the previous week. During the same period 1,417 cases were reported from the L.C.C. elementary schools, compared with 1,152 in the previous week, and the average daily admissions to the L.C.C. fever hospitals were 53 compared with 39 for the previous week. During the same week 31 cases were notified in Stepney, 11 in Shoreditch, 7 in Bermondsey, making a total of 49 compared with 37 last week. There were no notifications of measles in the Port of London during the week under review. It should be emphasized that these figures refer to cases reported to the London County Council, from whose weekly returns they are taken. Measles is notifiable in certain metropolitan boroughs, the actual number and the conditions of notification varying from time to time. At present all cases of measles are notifiable in only one borough—namely, Fulham. In the boroughs of Battersea, Finsbury, Greenwich, Hampstead, Lambeth, Southwark, and St. Pancras the first cases of measles occurring within two months only are notifiable—that is, subsequent cases in a family are not notifiable unless an interval of two months has elapsed since the notification of the first case. In the boroughs of Shoreditch, Stepney, and Bermondsey notifi-

able cases are further restricted to children under 5 years of age.

In Scotland notifications of measles during the week have risen from 1,330 to 1,551, and the deaths from 17 to 20, the increase affecting chiefly Glasgow, where the figures rose from 1,020 to 1,245, while the deaths rose from 11 to 17. In Edinburgh the notifications rose from 119 to 121, while the deaths fell from 4 to 2. In Belfast the cases fell from 789 to 577, and the deaths from 25 to 19. In Dundee the cases rose from 18 to 38, and in Aberdeen from 7 to 10.

Medical News

A public meeting has been arranged on Thursday, March 3, at 8 p.m., at the Royal Society of Arts, 18, John Street, Adelphi, W.C., for a debate on "The True Path to National Fitness." The chair will be taken by Professor V. H. Mottram, and the speakers will include Professor W. E. Le Gros Clark, Miss Marjorie E. Green, and Professor J. R. Marrack. Tickets (6d. and 1s.) may be obtained at the door or from the honorary secretary, Committee against Malnutrition, 19c, Eagle Street, Holborn, W.C. A small book, *National Fitness—a Brief Essay on Contemporary Britain*, was published on February 8 by Messrs. Macmillan Ltd. at 6s. net. Some of the above speakers participated in the preparation of this book, which contains a foreword by Major-General Sir Robert McCarrison. The aim of the authors has been to provide in readable form the essential facts and figures for a critical study of this vital problem.

The following postgraduate courses will be held at the Hamburg Institute for Tropical Hygiene during 1938: (1) March 21 to April 9, course for ship doctors in the diagnosis and treatment of the most important tropical diseases occurring on shipboard; (2) July 11 to 30, Spanish course in tropical medicine for doctors, veterinarians, and zoologists; (3) October 3 to December 3, international course in tropical medicine and hygiene for doctors, veterinarians, and zoologists. Further information can be obtained from Institut für Schiffs- und Tropenkrankheiten, Bernhard Nochtstrasse 74, Hamburg, 4.

A discussion on illumination levels and comfort conditions as applied to the lighting, heating, and ventilating problem will be held at a joint meeting of the Illuminating Engineering Society with the Institution of Heating and Ventilating Engineers in the Hall of the Institution, Storey's Gate, St. James's Park, S.W., on Tuesday, March 1, at 7 p.m.

The German Institute of Psychological Investigation and Psychotherapy is organizing a postgraduate course from April 25 to 30. Further information can be obtained from the Institute, Budapesterstrasse 29/11, Berlin, W.62.

The eleventh annual meeting of the German Society for the Study of the Circulation will be held at Bad Nauheim on March 26 and 27; the main subject for discussion will be circulatory failure, and papers will be read on muscle tonus as a factor in post-operative shock; arterio-venous aneurysms; and capillary permeability. Further information may be obtained from Professor Eb. Koch, Kerchoff Institute, Bad Nauheim.

The fiftieth Congress of the German Paediatric Society will be held at Wiesbaden from March 26 to 31 in conjunction with the German Society of Internal Medicine. Further information can be obtained from the general secretary, Professor Goebel, Akademische Kinderklinik, Moorenstrasse 5, Düsseldorf.

On February 21 fire seriously damaged one of the laboratories at Elstree of the Lister Institute for Medical Research, but valuable apparatus and other material were saved. On the discovery of the fire some members of the staff fought it with hand extinguishers, while others removed most of the contents of the laboratory. Two fire brigades were called in, confining the outbreak to one building.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended February 12, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in Eire. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

(ii) 12 " " " "
(iii) 9 " " " "

* 577 cases in Belfast alone.
† After October 1, 1937, puerperal fever was made notifiable only in the Administrative County of London.

‡ Deaths from puerperal sepsis.
§ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

anti-diphtheritic serum; stethoscope, patella hammer, two thermometers, and a spare hypodermic syringe; pronotus and tab, aspirin, co. tablets; a tube for gastric lavage, which can also be used as a tourniquet; lastly a tracheotomy tube.

Primary Vaccination at the Age of 12

Surgeon Captain PERCIVAL M. MAY (London, S.E.10) writes in answer to "Chelsea" (*Journal*, February 19, p. 432): For a period of some thirteen years at the Royal Hospital School, Greenwich, where all new entrants had to be vaccinated, the total number of boys admitted was between three and four thousand. They were aged from 11 to 13 years, and there was a gradually increasing proportion (in 1930 28 per cent.) of primary vaccinations. The possibility of post-vaccinal encephalitis was ever in my mind, after I had become aware of such a rare sequel, but I never had a single case, and after adopting the intradermal "multiple pressure or prick" technique, as recommended and described by Leake (1927) of the U.S. Public Health Service, the number of cases of vaccinia, and the days of sickness from vaccinia morbidity, were markedly lowered. The vaccine employed was in all cases obtained from the Government Lymph Establishment and used within a week of its receipt.

Income Tax

Division of Partnership Profits

"QUERIST" is a partner with two other practitioners. Up to January 1, 1938, the profits were divided in the ratios of A 3/7, B 2/7, C 2/7, but as from that date the ratios have been 3/7, 3/7, 1/7 respectively. What alterations will this change necessitate in the division of the tax charged for 1937-8?

* The existing division is of course based on an alteration of the gross assessment on the old ratios. In fact the ratios should be those in which the profits have been divided for the year ending April 5 (or, say, March 31), 1938—that is, A 12/28, B 7/28, and C 9/28. When a reallocation of the gross assessment is made on the basis of these figures, and the appropriate deductions are made for each partner and the tax on the respective net amounts calculated, the alterations in the division of the tax assessed on the firm will be apparent.

Change in Partnership—Cash Basis

"CAPITAL" explains that A., B., and C. have been in partnership, and for some years have been assessed on the cash basis. A. is retiring on June 30, but will continue to receive his share of the cash received for work done prior to that date. How will this affect the income tax returns?

* It should be borne in mind that the "cash basis" is merely a convenient way of measuring the gross earnings of a practice. A. will not be chargeable to tax on the cash received after June 30. The sums he then receives will represent the realization of income earned prior to that date, and he will have accounted for tax on those earnings. As regards the period after June 30, B. and C. will presumably have the alternative of (a) departing from the cash basis in favour of bookings less a deduction for bad and doubtful debts, or (b) adhering to the cash basis provided that they include all receipts from the practice work—that is, those taken by A. as well as those shared by B. and C.

LETTERS, NOTES, ETC.

Insulin Therapy in Schizophrenia

Dr. G. W. B. JAMES writes: In the *British Medical Journal* of February 19 you kindly report a joint paper by myself and others on insulin therapy in schizophrenia. Your reporter concluded that the film projected to illustrate the manifestations of schizophrenia was taken by Kodak Ltd. I feel I must write to explain that the film was entirely taken by myself or my co-workers. I would ask you to correct the impression given that this film was taken by Kodak Ltd. and is therefore available in their medical library of films. The Medical Department of Kodak Ltd. has given much assistance in the editing of the film and in advising me in my early days as a film director, and I owe them a deep debt of gratitude. This letter gives me an opportunity of saying that I have long been keen on the cinema as a means of teaching, and I feel very strongly that it can be made to play a useful part in illustrating lectures on psychiatry.

"The Evolutionary Theory"

Colonel G. F. ROWCROFT, D.S.O., writes from Coonoor, S. India: In a review in your issue of November 27, 1937, p. 1071—"Experiments on Animals"—the reviewer says (1) that the Darwinian hypothesis has "abundantly justified itself." Has it? He likewise says (2) that the younger medical man of these days views with a detached interest the arguments of the opponents of evolutionary theory. In many cases, unfortunately, quite true. Why? He also politely states (3) that the logical anti-vivisectionist suffers from pseudo-paranoia, and that he ought to be "an anti-vaccinationist, a vegetarian, and an opponent of the germ theory of disease." Why? And that "many of them are all these things." Are they? Such remarks savour rather of ex-cathedra omniscience, and I venture to think would hardly be sustained by an accurate census. A few such, a very few, there may be; which only shows that you may find all kinds of ideas in any body of even educated men. An anti-vivisectionist need not necessarily subscribe to the above ideas; he is as much entitled to his own opinions as anyone else, and to stress that because he holds such opinions on certain points he must necessarily and logically "go the whole hog" and hold others which may be supposed to arise from them is simply to strain arguments ad absurdum. To answer (2) above: As regards the "evolutionary theory" (which your reviewer very rightly designates a theory, not a fact) I presume this is intended to mean the theory that man, *Homo sapiens*, has been evolved by slow degrees from an ape-like ancestry, this ancestry in its turn having been evolved from some unicellular organism. "Evolution" in the sense of progress and many forms of development all will admit, but not the above "theory." It is not only "younger medical men," but unfortunately the rising generation generally—not to mention their fathers—who largely believe in the theory, for two reasons: (a) they find it believed in by their elders as a proved fact, and (b) the seeming arguments for it are in many schools drilled into them from childhood, its manifest impossibilities being suppressed and the unanswerable arguments against it being withheld. They very naturally accept it. Imagining the theory proved, without any further inquiry they of course look on its opponents as benighted beings. As regards my opening remarks under (1), to say that the "Darwinian hypothesis has abundantly proved itself" is simply an *ipse dixit*. If its upholders really think so they must be remarkably easily satisfied. In a letter already too long it is impossible to argue such a point, but I may remark that Darwin himself saw endless objections to the belief, though he propagated it. Haeckel, a most subtle writer on the subject (but in whose arguments numerous fallacies can be detected by the careful reader), admitted that many of his illustrations were deliberately faked in order to make them fit the theory. In later years he was compelled to write: "Most modern investigators have come to the conclusion that the doctrine of evolution, and particularly Darwinism, is an error and cannot be maintained" (*Fundamentals*, vol. iii, p. 29).

Anxiety State Treated by Hypnosis

Dr. R. W. P. HALL (Windermere) writes: I feel that the following case is of interest in view of the length of time the symptoms had persisted, and also the complete lack of response to previous medical treatment. The patient, a woman of 39, married, no children, had been very nervous and sensitive from childhood. The remainder of the family, including her mother, were very unimaginative people who had no patience with her ailments. She had at various times been treated by means of sedatives and good advice, but in spite of these measures her symptoms became more marked and numerous. I first attended her after she had been carried back from a short walk, having had a "heart attack." On examination she was found to have a rapid irregular pulse, with shortness of breath and slight cyanosis. Other symptoms elicited, and confirmed by her husband, were: (1) insomnia; (2) dysmenorrhoea associated with severe neuralgia; (3) dyspepsia; (4) an overpowering fear of all social life on account of the heart attacks, which were an almost daily occurrence. Her idiosyncrasy towards sedatives was confirmed during the first day or so, and it was then proposed that she should have a course of treatment by hypnotic suggestion, to which she agreed. Beginning with the insomnia, all her symptoms cleared up in the course of fifteen treatments extending over seven weeks. The only drug given was gardenal, half a grain night and morning during the first three weeks, but

In May, when the Dutch Gynaecological Society celebrates its fiftieth anniversary, an international obstetrical and gynaecological congress will be held. The secretary of the congress is Dr. C. F. van Tongeren of Amsterdam. The subjects for discussion are eclampsia, thrombosis and embolism, and hormones.

The King has appointed Dr. Robert William Cooper and Dr. Norman Bennington Watch as Members of the Order of the British Empire (M.B.E.) for services rendered in connexion with the recent volcanic eruptions in the Mandated Territory of New Guinea.

Dr. Nanna Svartz-Malmberg, author of important work on intestinal bacteria and their influence on rheumatic diseases, has been appointed professor of medicine at the Stockholm Caroline Institute. She is the first Swedish woman to be appointed professor.

Professor Ernst Kretschmer, director of the Marburg University Neurological Clinic, has been elected a corresponding member of the Society of Neurology and Psychiatry of Buenos Aires.

A new journal dealing with the physiology and pathology of old age, entitled *Zeitschrift für Altersforschung*, began in January under the editorship of Professor E. Abderhalden and Professor M. Bürger. The journal will appear quarterly, and is published by T. Steinkopff of Dresden and Leipzig.

Dr. Milan Yovanovitch-Batut, doyen of the Yugoslav medical profession and doctor *honoris causa* of the Belgrade faculty of medicine, has recently celebrated his ninetieth birthday.

Sir Ernest Graham-Little, M.P., has been elected an honorary member of the Argentine Dermatological Society.

Dr. Georges Guillaumin, professor of neurology in the Paris faculty of medicine, has been elected president of the Société Médicale des Hôpitaux de Paris.

Professor Fernand Bezançon has succeeded Dr. Martel as president of the Académie de Médecine.

The editorship of the journal entitled *Archiv'o di Anthropologia Criminale, Psichiatria e Medicina Legale*, founded by Cesare Lombroso and subsequently edited by Carrara, has this year been handed over to Professor Leone Lattes, professor of forensic medicine at Bologna.

Dr. L. M. Pierron, general secretary and founder of the Federation of the Latin Medical Press, editor of *Acta Medica Latina* and founder and editor of the *Revue française de Gynécologie*, has been made a Commander of the Crown of Italy by the King of Italy.

The King Edward Hospital Fund for London has bought a special car for conveyance of radium in connexion with the Central Radium Pool which it has established for the benefit of London hospitals.

One of the largest tuberculosis hospitals in the world is shortly to be inaugurated in Buenos Aires. The Government has made a grant of 3,000,000 pesos (about £200,000) for its erection and of 1,000,000 pesos (£66,000) a year for its upkeep. When finished the hospital will stand fourteen stories high on a fifteen-acre site near the centre of the city, which is to be planted with pine, eucalyptus, and other trees with medicinal qualities. It will be equipped for the treatment of 1,200 indoor patients and for research, and will be the headquarters of a national anti-tuberculosis campaign.

A statue of Hippocrates, presented by Dr. Skeros Zervos of Athens, was recently unveiled at the Académie de Médecine.

The Japanese Minister of the Interior has drawn up a Bill for rendering compulsory periodical examination of all the inhabitants up to the age of 40.

According to official statistics for 1937 Belgium possesses 6,311 doctors, or one doctor per 1,315 inhabitants. In the large towns the number of doctors is much higher: Brussels has 1,370 (1 per 605 inhabitants), Antwerp 436 (1 per 1,068), Ghent 242 (1 per 889), and Liège 416 (1 per 605).

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

THE TELEGRAPHIC ADDRESSES are
EDITOR OF THE BRITISH MEDICAL JOURNAL, *Attitology Westcent, London.*

SECRETARY, *Medisecra Westcent, London.*
The address of the B.M.A. Scottish Office is 7, Drumshuegh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Sulphanilamide and Sulphaemoglobinaemia

Dr. JULIAN KASTELIAN writes from the Westminster Hospital: There appears to be a danger in the indiscriminate use of sulphur-containing barbiturates (for example, pentothal) intravenously for short anaesthetics. If the patient is receiving treatment with *p*-aminobenzenesulphonamide (that is, prontosil and related compounds) and minor surgical intervention becomes necessary, an intravenous barbiturate will often be considered. Should, however, a "thio" group be present, as is the case with pentothal, the patient is possibly in danger of sulphaemoglobinaemia. It would be interesting to learn if any such cases have been recorded.

The "Emergency Bag"

Dr. E. G. HOUSDEN (London, S.W.17), in replying to "Ex-Service" (*Journal*, February 5, p. 320), writes: During the past fifteen years in general practice I have evolved the following "emergency outfit." I use a single case, 15 in. by 10 in. by 5 in., containing: (1) a wooden box, 7½ in. by 6½ in. by 5 in., for dressings, pins, a small kidney dish, a rubber catheter, and strapping; (2) a wooden box, 4½ in. by 6½ in. by 5 in., for sutures, hypodermic syringe in spirit, needles, microscope slides, finger-stalls and vaseline, silver nitrate stick, and drugs (tablets for hypodermic administration: amyl nitrite, ephedrine, calomel, phenacetin, aspirin, Dover's powder; ampoules of coramine, adrenaline, salyrgan, S.U.P., and iodine); (3) diagnostic instruments—electrical set, sphygmomanometer, throat swabs, patella hammer, and tape-measure; (4) wallet containing national health insurance prescriptions and certificates, private prescription pad, and stationery; (5) tube of ethyl chloride and vaccination set; and (6) case of dressing instruments. The case can be so packed as to prevent rattling, and includes all immediate necessities.

Dr. C. C. H. CHAVASSE (London, W.9) also writes: The following is a useful collection: instrument case with scalpel, artery and one pair dissecting forceps, and scissors, preferably in spirit; 5-cm. hypodermic syringe in spirit in a case; cutting needles, staghorn beetle clips (Allen and Hanbury's), and silk and horsehair sutures; vaccination scarifier; eyelid elevator; tablets for hypodermic administration of morphine, atropine, digitalis, ergotin, hyoscine; corpora lutea ampoules, S.U.P. 36 in ampoules, and ampoules of adrenaline and morphine; one three-inch bandage, one elastoplast bandage, and one cellonall bandage, with packets of sterilized wool and gauze; bottles of iodine and of spirit; one tube or container of wool for the application of iodine; sodium bicarbonate, tannafax, insulin, anti-tetanus, gas gangrene, and

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

161 Essential Hyperpiesis

R. STEINERT (*Nord. med. Tidsskr.*, December 11, 1937, p. 2013) has undertaken a study of the vital statistics for the whole of Norway for the ten-year period 1925 to 1934 in a search for information which might throw light on the common assumption that essential hyperpiesis is increasing in frequency as a result of the increasing psychic and physical stress of modern life. His studies were limited to the deaths of persons over the age of 50, as hyperpiesis is seldom fatal under this age. Since apoplexy is a common sequel of hyperpiesis, he argued that the deaths from apoplexy in the period under review would give a clue to the frequency of hyperpiesis in the same period. Indeed the experiences of his hospital in Bergen suggest that this condition is the main cause of most fatal cases of apoplexy, the number of which varied little from year to year during the ten years studied. He believes therefore that hyperpiesis has not grown appreciably in frequency in this period. On the other hand, in the same period there was a remarkable rise in the number of deaths traced to chronic disease of the myocardium, the rise being 48 per cent. for men and 53 per cent. for women. Even after improved methods of diagnosis had been discounted in connexion with this rise a considerable portion of it must be held to be real and in conformity with the increase in chronic heart disease registered in most other civilized countries. The author does not think it legitimate, however, to argue from this rise in the frequency of deaths from chronic heart disease that there has been any corresponding rise in the frequency of hyperpiesis in the same period.

162 Toxicity of Sulphanilamides

M. MATTIOLI (*Rif. med.*, December 11, 1937, p. 1773) states that the use of sulphanilamide preparations has been chiefly reserved for infections of streptococcal origin, such as puerperal septicaemia, erysipelas, tonsillitis and Ludwig's angina, streptococcal septicaemia, streptococcal meningitis, and otogenic infections. Sulphanilamide has also been tried in certain conditions not due to streptococci—namely, cerebrospinal fever, gonorrhoea, and *B. coli* infections of the urinary tract. Toxic effects are usually associated with prolonged use of the drug, and consist in nausea, abdominal colic, morbilliform and maculo-papular eruptions, fever, acidosis, cyanosis, methaemoglobinaemia and sulphaemoglobinaemia, and agranulocytosis. These effects of the drug, which are not common, are often due to its irrational use, its employment for a long period, or its administration in febrile diseases of uncertain nature. Sulphanilamide preparations should be given only to patients in bed and under daily observation by the physician.

163 Mixed Leukaemia

D. SUCIC (*Wien. Arch. inn. Med.*, 1937, 31, 6, 317) refers to a dozen reports from the literature in which the existence of mixed myeloid and lymphatic leukaemia has been claimed, and describes a personal case which he believes to fall within this rare category. A male, aged 37, had severe hypochromic anaemia with moderate enlargement of the liver, spleen, and lymph glands; the white cells rose from 8,000 to 76,000 during the month before death, lymphocytes numbering 60 to 80 per cent., myeloblasts 5 to 35 per cent., and neutrophil myelocytes 1 to 4 per cent. (both giving a positive oxydase reaction), and neutropenia being constant. The diagnosis suggested by examination of an excised inguinal gland was lymphosarcoma; radiological examination of the bones, which, especially

in the pelvis and skull, showed numerous round or oval defects affecting chiefly the spongiosa, seemed rather to indicate a diagnosis of Kahler's multiple myeloma; Bence-Jones proteinuria was absent, however. Naked-eye and microscopical examinations after necropsy showed that the bony lesions were due to leukaemic hyperplasia of the marrow, together with generalized osteosclerosis and osteoporosis, of which the former occurred chiefly in the limbs and skull, the latter in the pelvis and spine. (Bony sclerosis and porosis have been previously described in myeloid more commonly than in lymphatic leukaemia, and even in one case in acute lymphatic leukaemia.) The macroscopic post-mortem diagnosis was leukaemia; from the histological discovery of numerous myeloblasts and myelocytes, chiefly in the lymph glands but also in the spleen, liver, parts of the marrow, kidneys, and tonsils, and of lymphocytes and lymphoblasts in the marrow, kidneys, spleen, and periportal tissue a mixed myeloid and lymphatic leukaemia was inferred, with preponderance of lymphadenosis in the marrow and viscera, and of myelosis in the lymph glands. Most probably, as in the majority of similar cases, this was an instance of the secondary establishment of myelosis in a patient who had suffered for some time from lymphadenosis.

Surgery

164 Gastric Acidity in Cancer of the Stomach

E. ASK-UPMARK (*Acta chir. scand.*, 1937, 80, 1-2, 931) records observations made at the University Hospital in Lund, Sweden, at variance with the statement passed on from one textbook to another that acidity of the gastric juice is a characteristic feature of cancer of the stomach. In the ten-year period 1927 to 1936 the diagnosis of cancer of the stomach in 186 cases at the author's hospital usually depended on operation or a post-mortem examination. In certain inoperable but radiographically characteristic cases no post-mortem examination was made. The gastric juice was examined in 101 cases, in thirty-four of which free hydrochloric acid was found. In seven other cases it was found only after the injection of histamine, and in yet ten other cases hydrochloric acid "might have been present had the fractional test been performed in all instances." It was significant, in the author's opinion, that the frequency with which hydrochloric acid was found varied greatly with the location of the disease. The amount of hydrochloric acid was in most cases moderate, but occasionally it was considerable. No relationship could be established between the patients' age and the frequency with which their gastric juice contained hydrochloric acid. The author concludes that the presence of free hydrochloric acid in the stomach, even in considerable quantities, does not necessarily justify the exclusion of the diagnosis of a malignant growth of the stomach.

165 Vesical Dysfunction following Excision of the Rectum

M. HILL, R. BARNES, and C. COURVILLE (*J. Amer. med. Ass.*, October 9, 1937, p. 1184) give a short survey of the results they obtained in an investigation of urinary symptoms in a series of twenty-two cases. This was undertaken to find out the incidence of vesical dysfunction following abdomino-perineal resection for carcinoma of the rectum. The results are also given of a questionnaire answered by fifty-nine surgeons. The number of patients who suffered from vesical dysfunction after rectal resection varied from 25 per cent. to 100 per cent., with the majority over 50 per cent. Retention of urine may be transitory, may last for several months, or may be permanent, according to the character and extent of damage to the

as she had been given luminal on a previous occasion with no effect one could not put down her improvement to this drug. Before she had the last two treatments she confessed to a great dread of her mother, who was due for a visit lasting ten days, and whose presence on previous occasions had precipitated more acute attacks. Suggestions countering this state of mind were given on the last two occasions, with the result that at the end of the ten days she asked her mother to stay for a further two weeks, and complete harmony reigned throughout the visit. Nine months have elapsed since her last treatment, and she has remained quite well in every respect.

Treatment of Pneumonia

Dr. R. LARKIN (London, S.E.1) writes: It is impossible to believe that the figures given in the leading article in the *Journal* of January 29 (p. 235) for the mortality rates for pneumonia, in this country as compared with America, are correct. If they are correct, and two out of every three pneumonia patients die in England and Wales to one out of every six in America, then it is time the profession learnt to rely on drug therapy instead of on antipneumococcal sera, oxygen, etc. I remember a doctor from Africa saying in the columns of the *Journal* that he found quinine excellent—so do I in Southwark. Here are the prescriptions I am constantly using—disregarding the possibility of tinct. camph. co. being precipitated as benzoic acid—and in practice I find it is nearly always effective in all types of pneumonia, except, of course, in bronchopneumonia:

R. Quin. sulph.	gr. xij
Acid. nit. dil.	gr. xij
Potass. citrat.	gr. xxiv
Tr. camph. co.	3 iij
Tr. scillae	℥ xxx
Salicin	gr. xij
Aq. chloroform.	3 ss
Aqua	ad 3 vj
Sig. One tablespoonful 4-hourly in water after meals.	
Aspirin	gr. v
{ Phenacetin	gr. iv
{ Caffein citrate	gr. i
Mitte 6. One half-tablet of each every four hours after medicine.	

If there is any associated bronchial catarrh, it is convenient to add *vin. ipecac.* and *tinct. senega* in small doses. If on academic grounds the incompatibility of the *tr. camph. co.* is objected to, a way out for the inclusion of the drug in treatment would be to give it in the form of *tinct. scill. opiat.* (B.P.C.) for the associated cough, for I believe it is essential.

Sex Hormone Therapy

Bayer Products, Limited, have just issued a booklet entitled "Sex Hormone Theory in Everyday Practice," which is a handy guide to those wanting easily available information in this difficult field of practice. In twenty-five pages seven chapters are devoted to the menstrual cycle, the cause of menstrual bleeding, treatment of menstrual disorders, treatment of disorders of pregnancy, endocrinology of the mammary glands, treatment of male disorders, and oestrin and cancer respectively. Then follows a list of Bayer hormone preparations and indications for treatment. The booklet can be obtained free on application to Bayer Products Ltd., Africa House, Kingsway, London, W.C.2.

A Medical Shorthand Writer

A familiar figure at meetings of medical societies has passed away in the person of Henry Dickinson, official shorthand writer to the Royal Society of Medicine, the Royal Medico-Psychological Association, the Royal Society of Tropical Medicine and Hygiene, the Medical Society of London, the Ophthalmological Society, the Hunterian Society, the Medico-Legal Society, and many other bodies. About forty years ago, a Pitman enthusiast, Dickinson eschewed a wider field for the employment of his flying pencil (or, rather, his pen, for the pencil he scorned as an unworthy tool) and specialized in the reporting of medical proceedings. It was a narrow line, but he cultivated it assiduously, and, in his prime, medical men would swear by "Dickinson's note." If a speaker had a suspicion that he had not said exactly what was attributed to him, such a suspicion was completely dispelled by the production of those copper-plate pages. There it was, in thick strokes and thin. His longest tenure was his reportership of the Medical Society of London, which went back for thirty-nine years. He was reporter for several of the bodies which amalgamated in

1907 to form the Royal Society of Medicine, and he remained reporter for that body until his death. Many years ago he published a small manual entitled *Medical Reporting in Pitman's Shorthand*, in which he gave the shorthand forms for between three and four thousand medical words and phrases, along with some good advice to those who record medical discussions or act as doctors' amanuenses. The student of the published proceedings of various medical societies in years to come, while he will probably never learn the name of the scribe who set them down in clear and orderly form, will have occasion to be grateful for his patient and skilful work.

Austrian Medical Stamps

Medical stamps are becoming slowly but increasingly popular in different countries. On December 5, her annual "Day of the Stamp," Austria issued an attractive set of nine stamps commemorating her most distinguished medical sons. The likenesses are extremely good, the portraits being effectively set against a dark background. Van Swieten is depicted in the sepia 5 groschen stamp, Auenbrugger on the red-8, and Rokitansky on the grey 12. Skoda looks characteristically pedantic and dull on the green 20 stamp, while Hebra's appearance on the violet 24 is that of a genial *bon-vivant*. The carmine 30 represents von Arlt and the violet-red 64 Theodor Meynert. Perhaps the most striking portraits are those of Joseph Hyrtl, the anatomist (olive green 40), and of Billroth (blue 60).

Magnifiers in Spectacle Frames

Dr. A. J. BALLANTYNE (Glasgow) writes: Dr. F. Oliver Walker's short communication in the *Journal* of February 12 (p. 339) was of interest to me as I have had magnifiers of very similar construction in use for many years. The arrangement was suggested to me by a one-eyed patient, who had fitted a skeleton watchmaker's glass by fixing it to his own spectacle frame. Taking his hint, I got Messrs. John Trotter Ltd., opticians in Glasgow, to make a similar fitting for trial. Since then many patients have used this contrivance with satisfaction. These have mostly been cases of amblyopia, where magnification enabled the patient to read. The lens of the watchmaker's fitting can be made of any convenient strength, and the arrangement has the advantage that, being worn as a spectacle frame, both hands are available for holding a book, and as the watchmaker's fitting folds up the spectacles go into an ordinary flat case.

Medical Books for Surgeons in Spain

The Organizing Secretary of the Spanish Medical Aid Committee (24, New Oxford Street, W.C.1) writes: I have received a request from Spain for the *Annals of Surgery*, 1937 (published by John Wright and Sons Ltd., Bristol), and *Surgery, Gynecology and Obstetrics*, 1937 (published by Baillière, Tindall and Cox). We are anxious to send these out to the surgeons who require them, but are equally anxious not to draw on our funds for this purpose if it can possibly be avoided, and we wonder, therefore, whether any of your readers would be prepared to send us these for use in Spain.

Albuminuria and Bromides

Dr. S. J. HAYLOCK (Southbourne-on-Sea) writes: In cases of albuminuria from whatever cause the intake of bromides in medicinal doses tends to aggravate the condition, and to cause skin eruptions, etc. Patients suffering from albuminuria are advised not to take table salt. I would suggest also that no form of bromide be prescribed for them.

Corrigenda

We are asked to correct an error in the report of the opening of the new premises of the Institute for the Scientific Treatment of Delinquency published at page 416 of our issue for February 19. Dr. E. T. Jensen, chairman of the Institute, in expressing thanks to Lord Roche, said that he envisaged "an international Institute of Criminology," not "a large national" one.

In the Analysis of Cases of Sympathetic Ophthalmia from Schools for Blind Children published last week at page 393, in the fifth line of the second column "ophthalmia neonatorum" should of course have been "sympathetic ophthalmia."

The date in the first line of the second paragraph of the description of Case 1 in Dr. R. Stuart Renton's letter in the *Journal* of February 19 (p. 422) should be December 17 and not December 7 as printed.

disk of a gramophone. After sufficient amplification a telephone was found to reproduce all the tones transmitted to the water by the membrane. The Wever-Bray phenomenon in the inner ear is easily explained with the help of the author's theory. Tinnitus is probably due to harmful currents in the diseased cochlea. A development of Kupfer's theory is the introduction of a form of electrotherapy with the object of neutralizing the harmful currents by currents of opposite direction and of suitable strength.

170 Subglottic Cancer of the Larynx

StCLAIR THOMSON (*J. Laryng.*, December, 1937, p. 803) describes a type of laryngeal cancer which is rare as compared with the more ordinary forms which originate on the surface or along the margin of the vocal cords. Subglottic cancer arises in the space below the vocal cord. The celebrated historical case of the Emperor Frederick belongs to this group. In a series of fifty consecutive cases of intrinsic cancer of the larynx treated by the author, thirteen, or 26 per cent., belonged to the subglottic group. These growths are not seen with the laryngeal mirror until they extend up to the vocal cord from below. Since the voice may remain unaffected until the vocal cord is involved, and the symptoms may be trifling, such lesions are apt to be advanced before they come under notice. A subglottic growth may even run its course without ever extending to a cord. For these reasons the prognosis in all cases of subglottic cancer is much less hopeful than in intrinsic cases limited to the cords. Of the thirteen cases in the series of fifty, seven died of recurrence: six were alive and free from recurrence three years later. When a subglottic growth is suspected it is often necessary to do a preliminary laryngofissure and inspect the neoplasm *en face* before it can be decided whether the condition can be dealt with adequately through the laryngofissure, whether a complete laryngectomy is necessary, or whether no operation should be done. If the subglottic growth has not reached the arytenoid region or spread as low as the cricoid cartilage and has not crossed to the other side, removal by laryngofissure can be quite successful in securing a lasting cure. Invasion of the anterior commissure itself often means spread of the disease through the cricothyroid membrane into the soft tissues of the neck, and the possibility of recurrence of disease in the scar of the wound is increased. For patients whose age or health forbids operation, or who refuse laryngectomy, treatment must be by irradiation.

171 Orbital Suppuration of Nasal Origin

SARGNON and PAUFIQUE (*Ann. Oto-laryng.*, October, 1937, p. 869) subdivide orbital infections of nasal origin into three clinical groups. A first group associated with maxillary sinus suppuration is rare. A second and common group is associated with an infection of the anterior ethmoidal and frontal sinuses. A third group, also rare, is associated with posterior ethmoidal and sphenoidal sinus suppuration. Children are more often affected than adults, and sometimes the diagnosis of meningitis is made until the orbital signs develop. In very young children ethmoid suppuration is the main cause, because the frontal sinus is very little developed and the sphenoidal sinus not at all. The slighter cases resolve spontaneously by a sudden discharge of pus from the nose and the gradual disappearance of the orbital signs. The more serious cases go on to abscess formation and require operation. Grave signs are immobility of the eyeball with dilatation of the pupil, anaesthesia of the cornea, paresis of the ocular muscles, and interference with vision. When an infected tooth is the cause of an orbital suppuration, this occurs practically always by way of a maxillary sinusitis. In children adenoids are a very frequent predisposing cause; rarely, foreign bodies in the nose and rhinoliths. A large proportion of the cases

clear up with conservative treatment—rest in bed, inhalations, sprays, and fomentations. In small children it is best to avoid menthol and to substitute Friar's balsam for inhaling. When an operation is needed a small external incision is made just above the medial palpebral ligament, and the frontal and ethmoidal sinuses can be explored through this incision. This is usually preferable to exploration by the endonasal route. In infants it is often sufficient to detach the periosteum until the point of osteitis is reached. A gauze drain is left in the incision, and neither the orbital contents nor the ethmoid sinuses need be opened. In adults a small opening is made into the frontal sinus, but no curetting of the sinus should be done.

172 Indications for Tonsillectomy

K. VOGEL (*Deutsch. med. Wschr.*, December 24, 1937, p. 1943) reports from the University Nose and Throat Department of the Charité Hospital in Berlin the attitude he and many of his colleagues adopt towards tonsillectomy for the relief of various local conditions, such as chronic tonsillitis, and of more general conditions, such as rheumatism. The figures Professor Vogel quotes are from Frankfurt and have already been published (*Med. Welt*, 1936, No. 49). They showed that tonsillectomy was followed by recovery in 72 per cent. of the cases of articular rheumatism and by improvement in 15 per cent. The recovery rate was as high as 94 per cent. in cases of acute articular rheumatism, whereas in chronic articular rheumatism only 52 per cent. were cured and 30 per cent. were improved after tonsillectomy. After quoting percentages of recoveries and improvements following tonsillectomies performed for other ailments, including rheumatic heart disease, glomerulonephritis, and gastro-intestinal disturbances, etc., Professor Vogel concludes that relapsing sore throats and tonsillar abscesses are effectively prevented by tonsillectomy provided no diseased portion of tonsil is left behind. Less certain are the effects of tonsillectomy on chronic pharyngitis, laryngitis, and bronchitis originally due to infections of the tonsils, for in such cases the secondary foci established are apt to persist after the removal of the primary focus. To be really effective, tonsillectomy should, therefore, be performed as early as possible. By the time rheumatic polyarthritis, nephritis, endocarditis, etc., have become established the chances of their being cured by tonsillectomy are comparatively small.

173 Laryngeal Tuberculosis

N. R. BLEGVAD (*Hospitalstidende*, November 23, 1937, p. 11) bases his observations on 1,773 cases of tuberculosis of the larynx treated at a Danish hospital between 1916 and 1934. Of the 1,369 patients whose subsequent fate was ascertained 74 per cent. were found to have died, while 26 per cent. were still alive. Of the survivors, 60.5 per cent. could be regarded as cured after an observation period of several years. Among those who had died were several in whom the tuberculosis of the larynx had healed before death. The author insists that it is more important to recognize tuberculosis of the larynx as early as possible than to distinguish it from such other diseases as cancer and syphilis. He disagrees with the common textbook statement that acute laryngitis in the subjects of pulmonary tuberculosis predisposes to laryngeal tuberculosis, for practically all his patients suffering from the latter disease had not previously been liable to attacks of hoarseness indicative of acute laryngitis. Occasionally tuberculosis of the larynx presents at the outset the picture of a severe catarrhal laryngitis reminiscent of an acute non-tuberculous laryngitis. The author warns against the too facile assumption that any laryngeal affection in cases of pulmonary tuberculosis must necessarily be tuberculous. A characteristic feature of the ulcerations of acute non-tuberculous laryngitis is the almost invariable symmetry of their distribution. The basic treatment of

nervous elements. Cellules or small diverticula may appear within two weeks. Paralytic atony of the bladder may affect one or both sides. Vesical disturbance may be due to injury to the sympathetic nerves, reflex action, cystitis, or inflammation, or trauma to the bladder itself. It is suggested by one surgeon that the fact that the lower centres for both bladder and rectum are in the same segment of the spinal cord accounts for the urinary symptoms. The technique recommended to avoid this complication consists of drainage of the bladder by an indwelling catheter or repeated catheterizations. It is also suggested that during operation it is important to stay close to the rectal wall in the course of resection, thus avoiding the nerves and hypogastric plexuses. Treatment of retention by an indwelling catheter is indicated as long as there is more than 50 c.cm. of retained urine. If cystitis develops it should be treated by lavage of the bladder with potassium permanganate solution (1 in 6,000) and instillation of silver nitrate (15 c.cm. of 1 in 1,000 solution). Three personal cases are fully described.

166

Asymptomatic Appendicitis

H. J. SHELLEY (*Arch. Surg.*, Chicago, October, 1937, p. 621) presents a series of statistics based on a group of 2,065 appendectomies which were carried out during abdominal operations the indications for which were not associated with the appendix; the patients gave no evidence of past or present appendical disease. Of 1,904 appendices examined microscopically one-third were either normal or relatively normal, less than one-third showed slight to moderate inflammation, and the remainder presented evidence of marked pathological change, such as tuberculosis, tumour, hyperplasia of the mucosa, mucocoele, and oxyuris in the lumen. It was seen that there was a definite increase in inflammatory changes in the appendix when inflammation occurred elsewhere in the abdomen. No evidence was found to indicate that inflammation in the appendix caused cholecystitis. There was an increase in the incidence of atrophic and inflammatory changes in the appendix with increasing age, particularly chronic obliterative appendicitis. Peri-appendicitis was found to occur in early and early middle life. It was clear that acute appendicitis, even with actual suppuration, could exist without any subjective or objective evidence of its presence. As it was shown that the incidence of post-operative complications and the mortality rate were not increased in comparison with a similar series of operations without appendectomy, it is concluded that in properly selected cases the incidental removal of the appendix is a safe procedure of distinct value.

Therapeutics

167

Advances in Insulin Treatment

H. C. HAGEDORN (*Schweiz. med. Wschr.*, January 8, 1938, p. 36) has confirmed the value of protamine-insulin and zinc-protamine-insulin in 300 cases. He finds both preparations useful in severe cases in which the evening dose of ordinary insulin has not an effect sufficiently prolonged to avoid hyperglycaemia until the morning dose, or, if increased to prevent such a happening, leads to hypoglycaemic attacks. Their effect in levelling the large daily variations in blood-sugar concentration is especially valuable in acute complications, and in the occasional cases in which diabetes coexists with hyperthyroidism. Four methods of use are described: (1) ordinary insulin given in the morning and protamine-insulin at night; (2) protamine-insulin twice daily; (3) protamine-insulin or zinc-protamine-insulin once a day; and (4) simultaneous injection at twenty-four-hour intervals, of zinc-protamine-insulin and ordinary insulin—for example, 48 and 8 to 12 units respectively. Zinc-protamine-insulin has a slower effect than protamine-

insulin. Cases show pronounced individual variations in response, but in general some 15 per cent. fewer doses are required with protamine-insulin than with ordinary insulin; and with zinc-protamine-insulin the economy reaches 30 to 40 per cent. With treatment by the zinc preparation there may be an overlapping of the effects of successive doses—a fact calling for special precautions in connexion with hypoglycaemia, of which the first signs may be very severe.

168

Strophanthin Therapy

K. MÜLLER (*Münch. med. Wschr.*, December 24, 1937, p. 2051) discusses the intravenous administration of strophanthin, and claims that it can now advantageously replace digitalis preparations given by mouth, provided great care be taken in dosage. He has given about 10,000 injections with complete success, except in one woman, who started vomiting after even small doses of strophanthin, so that the treatment had to be discontinued. One of his patients has, in the course of the last seven years, received over 1,200 injections, and has been enabled to carry out her household duties. This patient was suffering from chronic auricular fibrillation. Müller lays great stress on the necessity for adopting a correct technique and using only reliable preparations of strophanthin. Strophanthin should never be injected when the patient is already taking digitalis by mouth. Müller has almost given up the use of any adjuvants, such as caffeine, calcium, cardiazol, glucose, etc.; moreover, he states that glucose has the disadvantage of damaging the veins, which is of course to be particularly avoided in patients who may have to receive injections over long periods of time. The only drugs he allows are those which act as analgesics. As regards the indications for strophanthin, Müller gives it in all forms of cardiac insufficiency or failure, whether they be due to valvular or to myocardial disease, in angina pectoris and coronary thrombosis, and in the presence of actual or threatened heart failure in acute infectious diseases, and particularly in pneumonia. In the latter strophanthin is especially valuable, since, in contrast with digitalis, it acts on non-hypertrophied cardiac muscle.

Laryngology

169

Electrochemical Theory of Hearing

E. KUPFER (*J. Laryng.*, January, 1938, p. 16) puts forward a new theory of hearing based on electrokinetic phenomena at the marginal surface of the liquids and of the solid structures in the cochlea, the surfaces in contact carrying opposing electrical charges. When movement takes place in the liquids of the cochlea, started by movements of the stapes, the opposite pairs of charges are displaced and separated, and a potential is set up. The alterations in contact potentials lead to the perception of sound. In the inner ear conditions are present for the development of this difference of potential, the sensory hair cells and other solids dipping into the endolymph. Whenever relative displacement of the endolymph against the hair cells occurs the electric potential of the hair cells is rhythmically disturbed. The author's hypothesis was tested by certain fundamental experiments. Two insulated metal rods were suspended in a liquid, the upper end of one rod being attached to a prong of a tuning fork. The rods were connected by long wires to a four-valve amplifier in another room, the output terminals of the amplifier being attached to head-phones. When the tuning fork was set vibrating a musical tone was heard in the head-phones which had the same frequency as that from the tuning fork. The effect was independent of the electrode material: zinc, copper, or cardboard electrodes acted equally well. In another experiment the liquid was set in motion by a membrane connected with the

MENFORMON TABLETS

to reverse menopausal changes

"I cannot refrain from mentioning the treatment of the MENOPAUSAL SYNDROME with œstrin. Quite small quantities of œstrin by mouth (1,000 to 5,000 units) are usually sufficient to control the hot flushes, headaches and dizziness, and to induce a remarkable feeling of well-being; and rather larger doses have a miraculous effect on such sequelæ as pruritus vulvæ, atrophic senile vaginitis, vaginal ulceration and kraurosis."

Mapharside

AN IMPROVED ARSENICAL FOR THE
TREATMENT OF SYPHILIS.....

SOME ADVANTAGES OF 'MAPHARSIDE'

1. 'Mapharside' is practically a pure chemical substance.
2. 'Mapharside' solutions do not become more toxic on standing.
3. 'Mapharside' is ready for injection by simple solution of the ampoule contents—no neutralization is required.
4. 'Mapharside' permits treatment of syphilis with small doses of arsenic.
5. Reactions following use of 'Mapharside' are apparently less severe than those observed after the use of arsphenamine and neoarsphenamine.
6. 'Mapharside' is chemically and biologically assayed.

PARKE, DAVIS & COMPANY
50/54, BEAK STREET, LONDON, W.1.

'Mapharside' (meta-amino-para-hydroxy-phenyl-arsine oxide hydrochloride) is a potent spirochæticide which is the result of co-operative research by groups in two American Universities and the Research Department of Parke, Davis & Co. This compound contains 29 per cent. of arsenic and it is effective in a dosage approximately one-tenth that of arsphenamine.

Supplied in one-dose ampoules of 0.04 and 0.06 gm. Further details will be sent on request.

tuberculosis of the larynx was with universal carbon-arc or quartz-light baths, the latter being preferred when the patients were debilitated and febrile, and yielding as good results as the former. Supplementary treatment in 346 cases consisted of excisions, in 465 of galvano-cauterization, in thirty-four of amputation of the epiglottis, in 114 of injections of alcohol, and in nineteen of resections of the superior laryngeal nerve.

174 Chronic Otitis Media Treated with Urea

P. S. MERTINS (*Arch. Otolaryng.*, Chicago, November, 1937, p. 509) quotes a recent article by Holder and MacKay on the use of urea in the treatment of chronically infected wounds and sloughing cancers. A strong solution of urea through its solvent action on proteins relieves the odour of foul chronic wounds almost at once. Further, it has been shown that urea in solution is bactericidal yet almost totally non-irritating to living tissue. Encouraged by these observations the author tried the effect of urea in chronic middle-ear suppuration. The first patient treated had a radical mastoid cavity from which flowed a foul-smelling discharge, which did not improve in spite of daily cleaning. The cavity was dusted with urea crystals once, and this eradicated all odour within twelve hours. After this large amounts of the crystals were applied twice daily by the patient; this resulted in the cessation of discharge in a few days and a completely healed cavity in five weeks. Further trial with this method in similar cases gave equally good results. The treatment was then tried in chronic otorrhoea. Apparently it is quite safe to insufflate small amounts of the urea crystals in cholesteatomata. Urea absorbs moisture and will not cause any dangerous swelling in the tympanic cavity. In an elderly patient with chronic otorrhoea of twenty years' duration and signs of cholesteatoma the ear became dry and clean within ten days. Eleven other patients with chronic otorrhoea and large perforations were treated with great success by dropping a saturated solution of urea in the ear twice daily. In cases with small perforations the results were much less favourable. A limited trial was made in acute otitis also with indifferent results. Caking of the urea and blocking of small perforations need not be feared. The urea is easily removed by a few drops of sterile water, which readily dissolve the crystals.

Obstetrics and Gynaecology

175 Hysterosalpingography in Ectopic Pregnancy

E. BORTINI (*Ann. Ostet. Ginec.*, November, 1937, p. 1247) discusses at length the place of hysterosalpingography in the diagnosis of ectopic pregnancy. He first reviews the so-called characteristic signs shown by ordinary x-ray examination in the different varieties of extra-uterine gestation, and draws attention to their unreliability. A series of forty-eight radiographs taken after the injection of an opaque substance shows the superiority of this method. Details are given of eleven cases in which a diagnosis made by hysterosalpingography was subsequently confirmed at operation. The author concludes that hysterosalpingography, properly conducted, will indicate even the particular variety of ectopic gestation concerned; but he insists on the necessity for serial radiographs (in some of his cases as many as nine views were taken) and the strictest asepsis, and is of the opinion that it should only be done in doubtful cases and with everything in readiness for immediate operation if necessary.

176 Kraurosis of the Vaginal Cul-de-sac

M. A. LABHARDT (*Gynec. et Obstet.*, October, 1937, p. 302) describes a condition which he calls kraurosis of the vaginal cul-de-sac, and which he has seen on thirteen

occasions during the past few years. It consists of a stenosis of the upper part of the vagina, which is so rigid that dilatation is impossible without the help of instruments. The perivaginal tissues are hardened and inelastic. When examined with a speculum the vaginal walls and the portio vaginalis are seen to be studded with red points, or to be completely red, and, in advanced cases, are covered with granulations which bleed easily and secrete a purulent and blood-stained discharge. The external orifice is always very small, though the lower part of the vagina is normal. The patients complain of a blood-stained purulent discharge, a feeling of weight in the lower abdomen, and sometimes pains in the loins. The age of the patients was from 25 years upwards. All showed signs of ovarian hypofunction. It is considered that the perivaginal stenosis is the primary condition and that the vaginitis is secondary; it may be associated with cancer of the cervix. This was so in two of the author's cases. Diagnosis of the cancer is rendered difficult by the stenosis of the upper vagina. Treatment is by means of ovarian hormones, particularly folliculin. The vaginitis usually responds to this treatment, but the stenosis is not improved. Local treatment with silver nitrate is also used. When the stenosis is extreme incision is indicated to permit secretions to escape and to allow of local applications. In all cases it is imperative to exclude cancer of the cervix.

Pathology

177 Peranal Antidiphtheritic Immunization

H. HAMADA (*Acta derm.*, Kyoto, 1937, 29, 5-6, 123) reports experiments on rabbits and guinea-pigs to investigate the amount of peranally administered diphtheria antigen or antitoxin that might be absorbed through the lower part of the alimentary tract. The degree of immunity acquired was tested by skin reactions to dilutions of diphtheria toxin. In both rabbits and guinea-pigs there was no development of immunity after the peranal administration of anatoxin or antiserum. When, however, ox bile was given peranally fifteen minutes before the anatoxin or antiserum, some degree of immunity was acquired by some of the animals, but the results varied individually very much among the rabbits and guinea-pigs used.

178 Experimental Aortic Atherosclerosis

F. R. MENNE, J. A. P. BEEMAN, and D. H. LABBY (*Arch. Pathol.*, November, 1937, p. 612) have studied the deposition of cholesterol in the aorta as the result of feeding cholesterol, either dissolved in oil or free, to rabbits. In the aorta of a normal rabbit receiving over 100 grammes of cholesterol they found extensive subintimal deposits of cholesterol distributed according to the usual occurrence of such lesions in man and animals, together with a high blood cholesterol content and the deposition of cholesterol in other organs. In thyroidectomized rabbits and in intact rabbits receiving iodine to depress the thyroid function similar changes were found in less time and with the administration of less cholesterol (up to 92 grammes), along with reduced basal metabolic rates and a high content of cholesterol in the blood. In rabbits receiving up to 147 grammes of cholesterol, but given in addition desiccated thyroid to produce hyperthyroidism and a raised basal metabolic rate, deposition of cholesterol was less frequent and less extensive in the aorta and in other organs, and the blood cholesterol tended to remain normal. The theoretical implications of these results and the possible mechanism of cholesterol deposition in the aorta are discussed. The authors consider that their results support the view that the two primary conditions necessary to the development of atherosclerosis are an excess of cholesterol or its esters in the blood and stress due to mechanical factors affecting the circulation.

SALTAIR SURGICAL SERVICE

Guarantee
 "We guarantee to alter
 exchange or accept the
 return of any appliance
 without cost ordered by
 the Medical Profession,
 if not found suitable
 within fourteen days
 from date of supply."
 Salt and Son Ltd.

Several exclusive features warrant your consideration of **SALT'S PATENT COLOSTOMY BELT**

India-
rubber
bag which
can be
detached
at will for
cleaning.

Showing rubber
receiver with
pad fitting next
to body and
rubber flange
to prevent belt
becoming soiled.

This belt provides the greatest possible comfort for the patient condemned to the Colostomy life. It has special and exclusive advantages such as: detachable receiver, sterilizable by boiling; easy removal of bag without removal of belt; bag easily emptied and washed out; no crevices or metal fittings to hold faeces; smell reduced to a minimum; less bulk than in the old style; bags easily and economically replaced. In Salt's Corset and Belt book the fullest information is given about this particular appliance. Any interested doctor can have a copy of this book, post free per return, upon request.

A little booklet

with a big purpose

This booklet contains valuable information concerning the many useful functions of the crepe bandage in every-day cases. Written by an eminent medical authority, it is a handbook well worth possessing. The Norvic crepe bandage, known and recommended for its remarkable elasticity, which is arrived at by a special weaving process, does not contain rubber in any form. It is given special mention in this interesting booklet. POST FREE on application to:—

GROUT & CO., LTD.,
35, Wood Street,
London, E.C. 2.

A Scientific Support giving GREATER FREEDOM

The special feature of the Curtis Abdominal Support No. 1 is its even anterior-posterior pressure. This support is acknowledged by Medical men to be one of the finest available owing to the permanent positive pressure exerted where it is most needed. Model No. 1 is light in weight, comfortable and gives complete freedom at all times to the hips. It is suitable in the treatment of all forms of abdominal ptosis-visceropptosis; enteropptosis and gastropptosis; and it is frequently recommended for support of ventral hernia and scar tissue in the lower abdomen.

55, DARLEY ST., BRADFORD.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron content remains fresh and unoxidized indefinitely, and

injury to teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.
The Iron 'Jelloid' Company, Ltd., King George's Avenue, Watford, Herts.

CHILBLAIN cured in 36 hours

Striking testimony to Sphagnol Peat Ointment

Since few people can stop working because of chilblains some effective local treatment is essential. Sphagnol soothes and cools chilblains with the first dressing. And concerning Sphagnol's effectiveness, a doctor has written: "I found the preparations you sent me remarkably good, especially the ointment, which

cured an intractable chilblain in 36 hours." Signed —, M.D. Test Sphagnol personally. On receipt of a postcard we shall be pleased to send you a sufficient supply.

COATES & COOPER LTD., 94, CLERKENWELL ROAD, LONDON, E.C.1.

One can't discuss football now

One just *can't* discuss football and smoking at the same time, and do justice to either. So, here, we make no apology for talking facts about tobacco. Fact 1. WILLS' Cut Golden Bar has been on sale for the last 40 years—a long time. Fact 2. In spite of all the newer tobaccos, at about the same price, its popularity has steadily increased. Fact 3. There's nothing at all dramatic about it. The flavour is quite unobtrusive—hence smokers don't tire of it. Try it, and you'll see that this is so. You can get it in the Original form or Ready Rubbed—at 1/- an ounce.

W.D. & H.O. Wills.

WILLS' CUT GOLDEN BAR

Made by The Imperial Tobacco Company (of Great Britain and Ireland), Ltd. C-340

ASK YOURSELF THESE QUESTIONS:—

1. Have you a Sickness and Accident Policy ?
2. Is it a Permanent Contract ?
3. When do the benefits cease ?
4. Does it cover you against all the casual pursuits you may take up—flying, gliding, mountaineering, etc. ?

**THE ONLY POLICY THAT COVERS ALL REQUIREMENTS IS
THAT ISSUED BY YOUR OWN SOCIETY.**

Write for Leaflet "B29" to the Manager and Secretary.

How We Assist in the Purchase of Medical Practices

Scotland's Oldest Insurance Company is prepared to assist Doctors in the buying of Medical Practices or Partnerships. The purchase price is repayable over a term of years, and a Life Assurance Policy is taken out as a collateral security. This scheme makes it unnecessary for a Doctor to approach his friends to act as guarantors, and enables him to pay for his practice out of income. After the repayment of the loan, the Life Policy becomes a valuable asset to the Doctor.

Many Doctors have already established themselves in practice with the aid of the "Caledonian" Scheme. The Interest Rates are particularly moderate. *The Accountant's charges for investigating the practice and the Legal Fees for preparation of the deeds and documents in connection with the Loan are paid by the Company in completed cases.* Arrangements can be made to meet special cases.

Full particulars on application to the Head Office, or to any of the Company's Branch Offices.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — WOODBRIDGE, SUFFOLK

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. (Toll Call from London.)

Proprietors: The Norwood Sanatorium, Limited.

RUTHIN CASTLE, NORTH WALES

A Private Hospital or Clinic for the diagnosis and treatment of Internal Diseases (except Mental or Infectious Diseases).

The weekly fees are from 15 guineas a week, according to the room occupied; rooms with bathroom are from 21 guineas. The charges include all chemical, bacteriological, x-ray or other examinations advised by the doctors, and all the usual forms of treatment, in addition to board and lodging. There are no extra charges except for alcohol (when ordered) and laundry.

An examination and consultation fee of 15 guineas is charged on the first visit.

The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout.

Address: THE SECRETARY, Ruthin Castle, North Wales.

Telegrams: Castle, Ruthin.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

NORTHUMBERLAND HOUSE,

ROYAL AIR FORCE MEDICAL SERVICE.

Applications are invited from medical men for appointment to commissions in the Medical Branch of the Royal Air Force for entry in May, 1938.

Candidates must be of pure European descent. They must be British Subjects, the sons of British Subjects and registered under the Medical Acts.

Candidates must normally be under 28 *years of age* but as a temporary measure consideration will be given to candidates up to 31 years of age and will be selected after interview by a selection board without competitive examination.

Hospital appointments held since qualifying will, under certain conditions, qualify candidates for antedate of commission up to a maximum of one year; the age on entry may, if necessary, be increased by a period equal to the "antedate."

Selected candidates will be appointed to short service commissions (for three years extendible to five years) followed by four years' service in the Reserve, and will be eligible to be considered for Permanent Commissions after having completed their first year of service and during the whole period of their service on the active list. Officers selected for Permanent Commissions will be allowed to count their service on a short service commission towards retired pay or gratuity to permanent officers. Officers not selected for Permanent Commissions receive gratuity as follows on transferring to the Reserve:—

On completion of three years, £400. On completion of five years, £1,000.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, also form of application, may be obtained on application from:—The Secretary, Air Ministry (D.M.S.), Adastral House, Kingsway, W.C. 2.

Completed applications from intending candidates for the vacancies in May, 1938, must be received in the Air Ministry not later than March 15th, 1938.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in April, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1938.

CENTRAL MIDWIVES BOARD.

Applications are invited from registered medical practitioners for appointment as **SUPER-NUMERARY EXAMINERS** for the **BOARD'S EXAMINATIONS** for PUPIL-MIDWIVES at the following centres:

London, Bristol, Liverpool/Manchester. Applicants must hold appointments in connexion with maternity hospitals or departments, and must have had experience in teaching pupil-midwives. Preference will be given to those who are Fellows or Members of the British College of Obstetricians and Gynaecologists.

Applications by letter should be sent by not later than March 21st, 1938, to the Secretary, Central Midwives Board, 23, Great Peter Street, Westminster, London, S.W.1, from whom further information can be obtained.

UMTATA HOSPITAL BOARD.**SIR HENRY ELLIOT HOSPITAL.****APPOINTMENT OF SENIOR RESIDENT MEDICAL OFFICER.**

Applications are invited from qualified Registered Medical Practitioners for the above-mentioned post. The salary attached to this position, which is whole-time, is at the rate of £600 per annum, plus free house, water, light and sanitation. A double-storied dwelling-house is shortly to be erected in which the successful applicant will be required to reside, but pending its completion he will be allowed an amount of £10 per month in lieu of quarters and incidental costs.

The successful applicant is to assume duty on July 1st 1938, and to enter into contract of service for three years (which may be renewed), the first year to be on probation.

The Hospital has 154 beds (22 European, 132 Native), but this accommodation will be increased by approximately 60 beds in the near future. Duties include assisting at operations, anaesthetics, radiology, the general ward work of a resident medical officer, lecturing to nurses and the general superintendence of the whole Hospital.

Applicants to state full particulars of:

(1) Their Medical and, in particular, Radiological and Surgical experience.

(2) Nationality, age, and whether married or single.

(3) Whether fully conversant with both English and Afrikaans.

Applications, with copies of three recent testimonials and health certificate, must be lodged with the undersigned not later than noon on March 15th, 1938.

Umtata, C. E. BEVAN, Secretary
Cape Province, South Africa.

COUNTY BOROUGH OF BOLTON.**RESIDENT ASSISTANT MEDICAL OFFICER.****BOROUGH ISOLATION HOSPITAL.**

Applications are invited from duly qualified medical men (or the position of Resident Assistant Medical Officer).

Candidates must have had experience in the treatment of cases of infectious disease in an Isolation Hospital. The duties will include the medical care of patients in the Isolation Hospital, assisting at the male Venereal Diseases Clinics, and such other work as the Medical Officer of Health may direct.

The person appointed will be required to reside at the Isolation Hospital. The salary will be £450 per annum, together with board and residence, valued at £150 per annum. Married quarters are not available. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the selected candidate passing a medical examination.

Forms of application, with particulars of the duties, may be obtained from the Medical Officer of Health, Howell Croft, North, Bolton, and completed applications, with copies of three recent testimonials, should be sent to the undersigned not later than March 7th, 1938. Canvassing, either directly or indirectly, will be a disqualification.

Town Hall, HAROLD B. ASHFORD, Town Clerk.
Bolton.

February 18th, 1938.

RADIUM BEAM THERAPY RESEARCH,
at the Radium Institute,
1, Riding House Street, London, W.1.

ASSISTANT MEDICAL OFFICER, resident, salary £150. Six months' appointment from March 18th, 1938. Applications, stating age, qualifications and experience, with copies of three recent testimonials, to be sent to the Secretary, Radium Beam Therapy Research, not later than March 7th.

The selected candidate will assist with the working of two five-gramme Radium units, and will have the opportunity of combining post-graduate studies with this appointment.

COUNTY OF DORSET.**MEDICAL OFFICER OF HEALTH**
for Shaftesbury Borough, Shaftesbury, Sturminster and Sherborne Rural Districts and Sherborne Urban District and
ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited from medical practitioners not exceeding forty years of age for the joint whole-time appointment of Assistant County Medical Officer and Medical Officer of Health for the Shaftesbury Borough, Shaftesbury, Sturminster and Sherborne Rural Districts and the Sherborne Urban District (population about 31,000). The appointment as Medical Officer of Health will, in the first instance, be in respect of the first three named districts only and in respect of the last two named districts when vacancies occur.

The salary for the combined appointment will be £800 per annum, together with a travelling allowance of £100 per annum, an office allowance of £50 per annum, and necessary out-of-pocket expenses according to the scales now in force.

Applicants must be qualified in accordance with Article 8 of the Sanitary Officers' (Outside London) Regulations, 1935, and hold the Diploma in Public Health or similar qualification.

The candidate appointed will, as regards his duties as Assistant County Medical Officer, come under the direction of the County Medical Officer of Health, and will be required to perform such duties as may be from time to time prescribed. As regards his duties as Medical Officer of Health, he will be subject to the control and direction of the District Councils concerned.

The post will be designated 'under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. He will also be required to reside within the area for which he is Medical Officer of Health, and to take up his appointment on July 1st, 1938.

Candidates must apply on the prescribed form, to be obtained from the undersigned, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than Saturday, March 12th, 1938.

Canvassing in any form will be a disqualification. County Offices, C. P. DRUTON,
Dorchester, Clerk of the County Council.
February 15th, 1938.

LANCASHIRE COUNTY COUNCIL.**BIDDULPH GRANGE ORTHOPAEDIC HOSPITAL.**

Applications are invited from duly qualified and registered Medical Practitioners for the following posts at the above Hospital, which contains 88 beds:

SENIOR HOUSE SURGEON (duties to commence May 1st).—Salary £250 per annum, together with board, residence and laundry. Candidates must have had experience in a general hospital. Preference will be given to candidates who have had orthopaedic experience.

JUNIOR HOUSE SURGEON (duties to commence April 1st).—Salary £200 per annum, together with board, residence and laundry. Preference will be given to candidates who have held resident hospital appointments, and who are competent anaesthetists.

Both appointments will be for a period of six months in the first instance, and for a further six months at the option of the Council, but will not be renewable after that time.

Applications, with copies of two recent testimonials, should be sent, not later than March 3rd, 1938, to Dr. F. HALL, School Medical and Child Welfare Department, County Offices, Preston. County Offices, GEORGE EHTERTON,
Preston, Clerk of the County Council.
February, 1938.

THE URBAN DISTRICT COUNCIL OF DAGENHAM.**DEPUTY MEDICAL OFFICER OF HEALTH (Male).**

Applications are invited from duly qualified medical men for the post of Deputy Medical Officer of Health. Preference will be given to candidates possessing the Diploma of Public Health or an equivalent qualification.

Commencing salary £600 per annum, rising by annual increments of £25 to £750, subject to superannuation deductions. The gentleman appointed will be required to devote the whole of his time to the duties of the office, which consist mainly of work in the Maternity and Child Welfare Department, but may also include duty in any section of the health services of the district.

Experience in ante-natal and maternity and child welfare work is essential. Opportunities will be available for acquiring experience in Public Health administration.

Application forms and further particulars obtainable from the Medical Officer of Health at the under-mentioned address upon receipt of a stamped addressed foolscap envelope. Closing date, March 14th, 1938. Canvassing disqualifies.

Civic Centre, Essex, F. W. ALLEN, Clerk of the Council.
Dagenham, Essex.
February 15th, 1938.

MONMOUTHSHIRE COUNTY COUNCIL.**ASSISTANT MEDICAL OFFICERS (female).**
(1 permanent and 1 temporary.)

The Council invite APPLICATIONS from duly qualified and registered Medical Practitioners (females) not exceeding 35 years of age, holding a Diploma in Public Health and State Medicine, for the appointment of ASSISTANT MEDICAL OFFICER, to undertake mainly the Medical Inspection and Treatment of School Children and, in addition, Maternity and Child Welfare work, and the investigation of Sanitary Conditions generally.

Experience in the correction of errors of refraction and the administration of anaesthetics will be essential.

There are two appointments, one Permanent and one Temporary.

The salary for the Permanent Post will be £500 per annum, rising by annual increments of £25 to £750, and for the Temporary Appointment £400 per annum, with third-class rail fares and subsistence allowance according to the Council's scale.

The successful candidate will be required to act under the direction and supervision of the County Medical Officer, to devote whole time to the service of the County Council, and to reside in such place as the Council may determine.

The Permanent Post will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

A schedule of the Duties to be performed, together with Conditions of Appointment and a Form of Application, can be obtained from the undersigned, to whom applications, accompanied by copies of not more than three recent testimonials, are to be sent by March 1th, 1938.

D. ROCYN JONES,
The County Hall, County Medical Officer,
Newport, Mon.
February 14th 1938.

CITY OF ABERDEEN.**REGIONAL MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.**

The Town Council of Aberdeen are prepared to receive applications for the appointment of Regional Medical Officer for Maternity and Child Welfare for the City of Aberdeen and for the Counties of Aberdeen and Kincardine.

Applicants must be registered Medical Practitioners and must hold a Diploma in Public Health or equivalent qualification. They must also possess qualifications enabling them to act as Supervisor of Midwives in terms of the Maternity Services (Scotland) Act, 1937.

The successful applicant will act as Assistant to the present Medical Officer for Maternity and Child Welfare until the retire of that Officer on June 30th next. On appointment, the salary will be £850 per annum and will be increased to £900 per annum on the retire of the present Medical Officer, rising to £1,000 per annum by annual increments of £50, with placing on the scale according to qualifications and experience. The office is an established post under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. Applications will be entertained from candidates up to the age of 48 years.

Applications, stating age, qualifications and experience, together with one copy of three recent testimonials, should be lodged with the undersigned not later than March 14th, 1938, from whom also can be obtained details regarding duties, terms of service, etc.

Town House, G. S. FRASER, Town Clerk.
Aberdeen.
February 14th 1938

BARRY URBAN DISTRICT COUNCIL.**ACCIDENT AND SURGICAL HOSPITAL.**

Applications are invited for the post of **RESIDENT SURGICAL OFFICER**, to commence duties as soon as possible. Salary at the rate of £350 per annum, rising by two increments of £50 per annum to £450, together with board and lodging; the appointment to be terminated by three months' notice on either side.

Candidates must be capable of performing major surgical operations. Preference will be given to applicants holding higher surgical qualifications and able to assist in carrying out the X-ray work of the Hospital. The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

The successful candidate will act under the direction of the Medical Superintendent and the Surgeon.

Applications, stating age and full particulars with regard to experience, with copies of three recent testimonials, to be sent to Dr. E. J. DAVIS, Medical Officer of Health, Public Health Office, Barry, Glam., so as to reach him not later than March 4th, 1938.

Council Offices, T. D. HOWTILLS, Clerk to the Council.
Barry.
February 14th, 1938.

LONDON COUNTY COUNCIL.

Applications invited from MEDICAL PRACTITIONERS of at least one year's standing to undermentioned positions. Experience in a general hospital for at least six months desirable. Married quarters not available.

ASSISTANT MEDICAL OFFICER (Grade I).
—Salary £350-£25-£425, with board, lodging and washing.

(a) **ST. LUKE'S HOSPITAL, LOWESTOFT, SUFFOLK.**—Experience in the treatment of non-pulmonary tuberculosis desirable.

There is no accommodation for a woman officer.

ASSISTANT MEDICAL OFFICER (Grade II)
—Salary £250 a year, together with board, lodging and washing. Appointment for one year only in first instance (renewable for a second year under certain conditions).

(b) **HIGH WOOD HOSPITAL FOR CHILDREN, Brentwood, Essex.**—Experience in children essential and in tuberculosis desirable.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division, 2a, County Hall, S.E.1, returnable by March 14th. Canvassing disqualifies.

COUNTY BOROUGH OF CROYDON.

ASSISTANT DENTAL SURGEON.

Applications are invited from licentiates in dental surgery for the post of whole-time Assistant Dental Surgeon at a salary of £450 per annum, rising by annual increments of £25 to £550. The duties will consist chiefly in the inspection, reporting and treatment of children attending elementary schools, and also dental work under the Council's Maternity and Child Welfare and Tuberculosis Schemes, and instruction in dental hygiene as required.

Applicants should have had at least one year's previous experience in the dental treatment of children, and the successful applicant will work under the supervision of the Medical Officer of Health and the Senior Dental Officer.

The post is designated as an established post under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the Medical Officer of Health, and accompanied by copies of not more than three recent testimonials, must be received by me not later than 11 a.m. on Monday, March 14th, 1938, in envelope endorsed "Assistant Dental Surgeon."

Town Hall, Croydon.
E. TABERNER, Town Clerk
February 15th, 1938.

CITY AND COUNTY OF BRISTOL.

ASSISTANT MEDICAL OFFICER OF HEALTH FOR AIR-RAID PRECAUTIONS.

The Corporation of Bristol invite applications for the post of Assistant Medical Officer of Health for Air-raid Precautions.

The gentleman appointed must have received training in Air-raid Precautions and have knowledge of anti-gas work. He will be required to devote the whole of his time to his duties and will not be allowed to engage in private practice. He will work under the direction of the Medical Officer of Health.

The appointment will be temporary in the first instance and will be subject to two months' notice on either side, and the selected candidate will be required to pass a medical examination.

The salary will be £500 to £700 per annum, according to experience.

Applications must be made on a prescribed form which may be obtained from the undersigned, and must be delivered at the Council House, Bristol, 1, not later than March 12th, 1938. Envelopes should be endorsed "Assistant Medical Officer of Health." Canvassing of members of the Council, either directly or indirectly, will disqualify.

The Council House, BRISTOL.
JOSIAH GREEN, Town Clerk.
February, 1938.

THE GUEST HOSPITAL, DUDLEY.

(General Hospital—135 Beds.)

The Resident Staff consists of a Resident Surgical Officer and two House Surgeons.

TWO HOUSE SURGEONS (Male) required. One to enter upon his duties on April 1st, and the other to commence on May 2nd. Salary at the rate of £100-£130, according to experience, with furnished apartments, board and laundry. Candidates must be fully qualified and registered. Duties include Medical, Surgical, Ear, Nose and Throat, Ophthalmic, Orthopaedic, Gynaecological work, etc. Applications, stating age, qualifications and experience, accompanied by copies of testimonials, to be sent to the undersigned.

H. RAYMOND HURST, House Governor and Secretary.
February 22nd, 1938.

SURREY COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of an Assistant Medical Officer (Male). Applicants must possess a qualification in Public Health, and should have had experience in the Medical Inspection of School Children and in Maternity and Child Welfare work.

The officer appointed will be required to undertake such other Public Health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County of Surrey, and devote his whole time to the work.

Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health and of the Board of Education, to the successful candidate passing a medical examination, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Staffing Regulations of the Council, which provide, *inter alia*, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Wednesday, March 9th, 1938.

Canvassing, directly or indirectly, will disqualify. DUDLEY AUKLAND, Clerk of the County Council
February 21st, 1938.

EAST SUSSEX COUNTY COUNCIL.

SOUTHLANDS HOSPITAL, SHOREHAM-BY-SEA.

CITY OF BIRMINGHAM. COLESHILL HALL.

DEPUTY MEDICAL SUPERINTENDENT.

Coleshill Hall, a colony for Mental Defectives of all ages and both sexes, consists of two divisions, five miles apart, situated at Coleshill and Marston Green respectively, each about ten miles from Birmingham.

Applications are invited for the whole-time appointment of Deputy Medical Superintendent for the Colony, aged 40 to 45, with experience in institutional administration. Salary according to experience (Scale £500-£700 per annum), subject to satisfactory service, plus emoluments consisting of unfurnished house, fuel, light and laundry, valued for superannuation purposes at £200 per annum. An additional £50 per annum will be granted if holding a recognized qualification in psychological medicine. All fees, allowances and remunerations received other than the foregoing must be repaid to the City Council.

The candidate appointed will be required to pass satisfactorily a medical examination and to be subject to the provisions of the Asylums Officers' Superannuation Act, 1909, as modified by the Asylums and Certified Institutions (Officers' Pensions) Act, 1918. The appointment will be subject to one month's notice on either side.

Application forms may be obtained from the Medical Superintendent, Coleshill Hall, Coleshill, near Birmingham, and must be returned to him not later than Monday, March 7th, 1938.

Council House, F. H. C. WILTSHIRE,
Birmingham, 1. Town Clerk.

CITY OF BIRMINGHAM. MATERNITY AND CHILD WELFARE DEPARTMENT.

TEMPORARY MEDICAL OFFICER.

A Temporary Medical Officer is required for a period of six months from April 1st. The work includes attendance at ante-natal and children's clinics. Applicants should have had considerable experience in work with mothers and children, including resident posts in a maternity hospital and in a children's hospital. The salary offered is £10 per week. The appointment cannot be terminated within the period named except for health reasons.

Applications, endorsed "Temporary Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, to be made on a form obtainable from the Medical Officer of Health, Council House, Birmingham, 3, and returned to him on or before March 5th.

COUNTY COUNCIL OF MIDDLESEX.

THE COUNTY (TUBERCULOSIS) SANATORIUM, HAREFIELD, MIDDLESEX.

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the above appointment. Candidates must be registered Medical Practitioners who have held resident appointments in a General Hospital. Experience in the diagnosis and treatment of tuberculosis will be an additional qualification. Salary £250 per annum, with board, lodging and laundry.

The officer appointed will work under the direction of the Medical Superintendent, and will devote his whole time to official duties.

The appointment (which does not at present carry any superannuation rights, will be subject to medical examination and is terminable by one month's notice on either side) is for a period of six months in the first instance, and may be extended for an additional six months.

Applications, stating age, qualifications, and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 5th. Relationship to any member or officer of the Council must be disclosed in the application.

Application forms are not provided. Envelopes must be endorsed "Junior Assistant Medical Officer, Harefield Sanatorium." and sent, directly or indirectly,

C. W. Clerk of the County Council.

APPOINTMENT OF HOUSE PHYSICIAN

Applications are invited for the appointment of House Physician, vacant April 1st, 1938.

The appointment is one of four Resident Medical posts which occur periodically during the year, and is for a period of six months, with salary at the rate of £100 per annum, and board, apartments and laundry.

Candidates must be legally qualified and registered.

Selected candidates will be required to attend a meeting of the Medical Committee for interview on March 6th.

Applications, stamped, with copies of testimonials, to be sent to the undersigned not later than March 7th.

L. I. KNOWLES,
Secretary.

ST. PETER'S HOSPITAL FOR STONE, ETC. Henrietta Street, Covent Garden, W.C.2.

The Office of HOUSE SURGEON will fall vacant on April 1st, 1938, and applications are invited from male candidates with previous experience in a similar office at a General Hospital. The salary offered is at the rate of £75 per annum, with board, lodging and laundry.

At the expiration of six months' term of office, and subject to the recommendation of the Medical Committee, the House Surgeon is appointed Resident Surgical Officer for a further similar period. Candidates should therefore be prepared, if successful, to remain at the Hospital for twelve months in all.

Applications, accompanied by copies of testimonials, should be forwarded to reach the undersigned not later than the first post on Tuesday, March 8th, 1938.

BEECHY ROGERS,
Secretary.

ST. JOHN'S HOSPITAL, LEWISHAM, S.E.13.

Applications are invited for the appointment of RESIDENT SURGICAL OFFICER (Male), which becomes vacant on April 1st next. Candidates should have been qualified as General Practitioners, and should have had one year's experience of hospital appointments. Preference will be given to those holding a senior surgical qualification. The appointment is for twelve months at a remuneration of £200 p.a., with the addition of Resident Staff Panel Fees. Applications, with copies of testimonials, should reach the undersigned not later than Tuesday, March 8th.

J. C. GILBERT,
Secretary-Superintendent.

THE NATIONAL TEMPERANCE HOSPITAL. Hampstead Road, N.W.1.

Applications are invited for the following posts:

RESIDENT MEDICAL OFFICER (Male). Salary £175 per annum, board, residence and laundry allowance.

CASUALTY OFFICER (Male). Salary £120 per annum, board, residence and laundry allowance.

The appointment is for a period of six months in each case, as from April 1st. Preference will be given to those who have held resident posts. Candidates must submit applications, stating qualifications, age, etc., with copies of not more than three testimonials, by Monday, March 7th, addressed to the Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN. Hackney Road, London, E.2.

HOUSE PHYSICIAN required April 1st, 1938. EAR, NOSE AND THROAT HOUSE SURGEON required April 1st, 1938.

Six months' appointments. Salary at the rate of £100 per year, with board, lodging, and laundry in each case.

Applications must be made on forms to be obtained from the undersigned, and must be sent in, with copies of not more than four testimonials, on or before March 7th, 1938.

CHARLES H. BESSELL,
February 10th, 1938. Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN. Hackney Road, E.2. (204 Beds.)

The Committee have applications for the post of ASSISTANT PHYSICIAN, with charge of Ear, Nose and Throat, from candidates who must be Fellows or Members of the Royal College of Physicians of London.

Attendance in the Out-patient Department required at present on Saturday morning, but possibly also on another day, to be arranged later.

An honorarium to cover travelling expenses will be paid.

Applications, with copies of three recent testimonials, should be sent to the undersigned, from whom further particulars may be obtained.

CHARLES H. BESSELL,
February 21st, 1938. Secretary.

DEVONSHIRE ROYAL HOSPITAL, Buxton, Derbyshire. (300 Beds.) (A National Hospital for Rheumatism and Allied Diseases.)

RESIDENT MEDICAL OFFICER (male), salary £200 per annum, or **HOUSE PHYSICIAN (male),** salary £150, rising to £175 after three months' service (and prospects of promotion to Resident Medical Officer), with fully qualified and registered. Candidates must be for a minimum period of six months. The appointments are for a minimum period of six months.

Applications, endorsed "Medical Appointments," stating age, experience and qualifications, and whether application is made for one or either post, together with copies of three recent testimonials, must be forwarded without delay to the undersigned, from whom any further particulars may be obtained.

Considerable orthopaedic experience is available, and the appointments offer special facilities for gentlemen preparing a thesis or wishing to undertake special work, as the Hospital contains all the necessary laboratory and other facilities for research. Canvassing will disqualify.

By Order of the Committee of Management,
A. PRESTON TURNER,
General Superintendent and Secretary.

BRIGHTON COUNTY BOROUGH MENTAL HOSPITAL, Haywards Heath, Sussex.

Appointment of **SECOND ASSISTANT MEDICAL OFFICER.** Applications are invited for the above post. Salary £500 per annum, increasing by £50 per annum on approved service to £600 per annum with an addition of £50 per annum for holding or becoming the holder of the D.P.M. The age of the candidate should not exceed 35 years. A cash allowance of £75 per annum will be given until a house is provided, during which time a charge will be made for meals taken in the Hospital when on duty. A similar allowance will be made to an officer desirous of having full board and lodging in the Hospital, but in that event the charge will be at the rate of £100 per annum.

The appointment will be subject to the provisions of the Asylums Officers' Superannuation Act, 1909.

Applications, with copies (not originals) of three recent testimonials, stating General Hospital, Mental Hospital and Laboratory experience, and to be sent to the Medical Superintendent and to be received by Thursday, March 3rd, 1938.

APPOINTMENTS.—Contd.**SUDAN MEDICAL SERVICE**

ONE MEDICAL INSPECTOR is required for
the Sudan Medical Service to proceed to the
Sudan at the end of June, 1938.

The selected candidate will be required to take
the Course at the London School of Tropical
Medicine, from April 4th, 1938, to June 24th,
1938. Fees and a subsistence allowance provided
by the Sudan Government.

Candidates must be British-born, single, under
thirty years of age, and have held a Resident
appointment in a large General Hospital. Pay
in the Sudan commences at £E.720 a year, rising
to £E.1,200 after thirteen years' service. On con-
firmation of his appointment the selected candi-
date will be eligible for pensionable service.

Applications (in writing only) with copies of
recent testimonials, should be made to Dr.
Hodson, 69, Harley Street, W.1.

WARNEFORD GENERAL HOSPITAL,
Leamington Spa. (164 Beds.)

Required a RESIDENT HOUSE PHYSICIAN
to commence on March 28th. Six months'
appointment. Salary £150 per annum with board
and laundry.

Applications from qualified registered Medical
Practitioners, stating age, status, and full particulars,
together with three testimonials, should be sent
to the undersigned by Wednesday, March 9th, 1938.

EDWARD L. WIRGMAN,
House Governor and Secretary.

WARRINGTON INFIRMARY AND DISPENSARY.

The post of **THIRD RESIDENT** will fall vacant
on April 1st, 1938, and applications are invited
from male candidates, who must be duly qualified
Medical Practitioners, and unmarried. Salary at
the rate of £150 per annum, with board, lodging
and laundry.

At the expiration of six months' term of office,
and subject to the recommendation of the Medical
Board, the Third Resident is appointed Senior
Resident (Salary £175 p.a.) and then Senior
Resident (Salary £250 p.a.) for similar periods.
Candidates should therefore be prepared, if
successful, to remain at the Hospital for eighteen
months in all.

Applications, stating age and qualifications,
accompanied by copies of three recent testimonials,
should be sent in not later than first post on
Tuesday, March 8th. Chosen candidates will be
interviewed on Friday, March 11th, 1938.

By Order,
HENRY L. BOOT.

Superintendent and Secretary.
February 22nd, 1938.

Response to Minadex observed in over 1,000 Children convalescent from fevers

In 6 oz. bottles, 2/6. 12 oz.
4/6; 80 oz. winchesters, 22/6.
Less usual discount. These
prices do not apply in Eire.

SYRUP MINADEX enables practitioners to give one tonic where two were needed before. It combines, in one effective and pleasant preparation, the active principles of both Syr. Ferri Phosph. Co. and Cod-Liver Oil, together with reinforcing "trace" minerals.

At a leading London fever hospital Syrup Minadex is employed as the sole tonic for the children's wards. In two years over 1,000 children have received it there and a testimony* demonstrates how valuable a part of the ward routine it has become.

Any child not eating well — straight on to Minadex. That is now their rule. "The speedy way in which Minadex restores appetite is quite remarkable. And the evident enjoyment of Minadex by all children bears full witness to its acceptable flavour... A much larger dose of iron can be tolerated by children when given as Syrup Minadex and, contrary to expectation, Minadex

is slightly laxative. We consider ourselves fortunate to have found a tonic so safe that we can prescribe it for every case from whooping cough to measles, even at the acute stage.

"... Always can we be confident that Minadex will have a dependable restorative effect."

Nelson New Loose-Leaf Publications

KEPT ALWAYS NEW BY 250 OR MORE REPLACEMENT PAGES
ISSUED EVERY SIX MONTHS • THESE VOLUMES CAN NEVER GROW OLD

Nelson Loose-Leaf Medicine

Published in nine volumes including Index Volume
Research Service and Consulting Bureau for Information
Editor-in-Chief WILLIAM W. HERRICK, M.D.
Professor of Clinical Medicine, College of Physicians and Surgeons, Columbia University, New York.

Published with the co-operation of Advisory Boards of the foremost authorities and about 800 of the leading physicians and surgeons of America, England, and the Continent, who have contributed the vastness of their knowledge to make these publications most scholarly, practical, and up-to-date systems.

Always Up to date

The Nelson Practice of Medicine is arranged in loose-leaf form so that obsolete chapters may be removed and revised chapters inserted, that every new description may be incorporated in the volumes and every article be kept thoroughly up to date. Each subscriber receives five hundred or more new pages annually. The Nelson system is a living, growing medical library—a mirror to present-day medicine.

Kept up to date every six months with 500 or more new or revised pages annually, practically a new volume, each year. The volumes avoid duplication and overlapping of subjects, only accepted and approved medicine is published. Follow-up results are stressed, obsolete methods are eliminated from the discussion. Tested new procedures are advised. References to comprehensive bibliographies are given.

Nelson Loose-Leaf Surgery

Published in nine volumes including Index Volume
Research Service and Consulting Bureau for Information
Editor-in-Chief ALLEN O. WHIPPLE, M.D.
Professor of Surgery, College of Physicians and Surgeons, Columbia University; Director of Surgical Service, Presbyterian Hospital, New York.

A New Practical System of Surgery

In the presentation of the surgery of any organ or system, it is essential to emphasize the pathology to be found, and to advise and describe such procedures as by actual follow-up studies have proved to give the most lasting and satisfactory results.

The Nelson Loose-Leaf Surgery is based on the definite experience of men whose practice has given them opportunities for the widest observation, and it places special emphasis on results as determined by actual and careful follow-up work. It covers in great detail Surgical Physiology, Pathology, and Medical Aspects of Surgery, Surgery in Special Conditions, Preoperative and Postoperative Care, and, above all, Operative Indications and Technic. Over 4,000 photographs and drawings.

"It is an extraordinary achievement on the part of the editors of this loose-leaf surgery to have been able to maintain the production of renewal pages at such a high level for so many years. Assurance of the reliability of this service is the most eloquent of all recommendations of this work to the coming generation of surgeons. . . ."

"Revised versions have arrived regularly, much of the original work has been discarded and replaced, and the present edition is as modern as it possibly could be."—The Lancet.

"The purpose of the volumes, with their handy device for insertion and removal of pages from time to time, is to mirror present-day medicine."—British Medical Journal.

Nelson's Consultation Service

An Added Service in Bringing the World's Medical and Surgical Data to You

Help in Solving Unusual Problems.

Nelson's Consultation Service is prepared to furnish you reprints of articles, or, if these are unavailable, photostats of articles, or, to save you time, abstracts or translations of articles in medical journals in foreign languages.

Thousands of Doctors Now Use It.

Thousands of men in the profession are constantly using this helpful service. A personal service furnished to all subscribers. Upon request, special abstracts and extracts from the British, American and foreign literature; bibliographies, reprints, and photostats, will be supplied without charge to all subscribers.

Please send me, without obligation, detailed prospectus, and full particulars of your part-payment plan for:

A SPECIAL SAFETY FEATURE

The special plug and socket provided with every Westric Trickle Charger is a guarantee against faulty or inefficient charging. By their use it is impossible to short circuit the battery or the charger, the chassis cannot become alive, there is no risk of shock, nor is it possible to accidentally reverse the charging current. This is just one of the many features found only in the Westric that ENSURES your battery being up to scratch always.

EMERGENCY SURGERY

By HAMILTON BAILEY, F.R.C.S. (Eng.)

REVIEWS FROM PREVIOUS EDITIONS.

"Mr. Bailey has achieved a great feat in writing this book, and many generations of medical men will thank him for it. . . . We do not see how this book could be bettered in any way."

—Medical Press and Circular.

"Mr. Hamilton Bailey has just cause to be proud of this volume, which can claim to be equal, and in many ways superior, to any book on the subject published hitherto."

—British Medical Journal.

London: SIMPKIN MARSHALL LTD.

PHILIPS

BIOSOL

With "Dorno" Filter
(Wave-band 4350-2900
A.U.)

Without Filter
(Wave-band 4350-1850
A.U.)

If you were purchasing a second ultra-violet lamp you would inevitably choose the 'BIOSOL,' for modern actino-therapy practice acknowledges the fact that in light treatment the majority of cases can be roughly classified in two groups:—

1. Cases which respond best to treatment with the wave-lengths found in the *natural* Solar spectrum (4350-2900 A.U.).
2. As in certain skin diseases, cases where the shorter or *non-terrestrial* wave-lengths emitted by the lamp can be beneficially applied. To such wave-lengths normally, the human body is not, of course, attuned.

The 'BIOSOL' is the only lamp provided with the "Dorno" Filter and which enables the wave-band to be selected according to the case. The 'BIOSOL' is on sale everywhere in the British Isles and any of the dealers listed on the opposite page will gladly arrange a demonstration for you. Write today for a copy of Publication No. X610.

Use the coupon on facing page.

**THE SCIENTIFICALLY DESIGNED
IRRADIATION UNIT—YOU CHOOSE THE
WAVE-BAND ACCORDING TO THE CASE!**

DO DEAF AIDS IMPROVE THE HEARING?

Recent reports of Research Work carried out under the auspices of the Medical Research Council indicate that the prolonged use of a suitable deaf aid does not in any way injure the hearing, but that in many cases considerable improvement occurs. There are deaf aid manufacturers who claim that the use of their instrument decreases the physiological degree of deafness. I make no such claim, not believing it proven, but my experience agrees with the medical reports in that there is a distinct improvement in mental appreciation, and that in many cases users of high quality hearing aids hear better even without the instrument as time goes on. In practice mental appreciation is far more important than physiological degree of deafness which is compensated for by

turning the volume control knob. The improvement of mental appreciation and the preservation of hearing are controlled by the use of the highest quality hearing aid available. The obvious choice is the AMPLIVOX, the first and most widely used High Fidelity hearing aid. I should be glad to send you full particulars of the AMPLIVOX hearing aids.

A. Edwin Stevens

Governing Director.

There are appointed representatives in Australia, New Zealand, Canada, South Africa, India, Eire, France, Belgium, Holland, Norway, Sweden, Denmark and Roumania.

QUICK AS AN AMBULANCE—

In emergency cases the opportunity of an X-ray examination is frequently the means of saving a patient's life. In other serious cases too, examinations carried out in the patient's own home are of the greatest possible value.

Within forty minutes of the arrival of a PORTABLE X-RAY Service Car, negatives are ready for inspection. More and more doctors are now using PORTABLE X-RAY Cars for visiting private homes, nursing homes, and hospitals.

A fully descriptive booklet will gladly be sent on request to the address below.

As good as a second right hand in the surgery

Yet another tremendous advance in surgery examination lamps—the Ceiling Model Terry Anglepoise. Out of the way, yet instantly to hand at a touch, pouring its strong, penetrating, concentrated beam right on to the spot, without any distracting glare in the user's eyes. Will practically reach to any part of the average surgery, thus avoiding awkward light-shifting when the patient must not be moved. Leaves both hands free. A perfect examining and dressing lamp. For sheer efficiency and convenience nothing can simply approach the ANGLEPOISE—adjustable to 1,001 positions at a finger touch—and poised at any angle. Simply marvellous for all "close" work as it throws the clear light necessary for extreme accuracy. It can be brought as close as required. Saves on light bills—a 25 watt bulb works like a 60! Scientifically built—every part superlatively made. Chromium plated arms, tireless springs—for perfect balance. In several models. Models for fixing to wall or table, and on smooth-running castors. "A Triumph for Terry Springs." From 50/- (U.K. only). Patented at Home and Abroad.

EARLY VEGETABLE DIET for OPTIMUM NUTRITION of INFANTS

It is now widely admitted that vegetable foods should supplement the milk diet of infants as early as possible. The difficulty in prescribing these foods, at an early age has however hitherto been the fact that the weak digestions of infants cannot successfully deal with the fibrous cellular tissue, which therefore causes intestinal irritation and consequent upset, frequently manifested by diarrhoea.

The Libby method of Homogenization disintegrates this tough, indigestible cellular fibre, thus enabling it to be easily eliminated, the 'bulk' however being in no way affected. This breaking down of the fibrous walls also has the advantage of enabling the full nutriment to be thoroughly assimilated.

Libby's Homogenized Vegetable Foods for infants are prepared in six scientifically-formulated combinations of Cereal, Vegetables and Fruit. These can be prescribed as needed to provide the necessary balance of Vitamins, Minerals and other essentials.

Samples together with clinical data and laboratory reports will be gladly supplied upon request to Messrs. Libby, McNeill & Libby Ltd., London, E.C.3.

to H.M. the King of Denmark.

—a natural water of tonic properties, used extensively by athletes
and invalids in Sweden.

RAMLÖSA

50 YEARS' REPUTATION FOR MEDICINAL AND TABLE USE

This famous natural mineral water is bottled at the source and slightly aerated with pure Carbolic Acid. The characteristics of "Ramlösa" are a relatively high Sodium Carbonate content in combination with an uncommonly low content of Calcium and Magnesium Salts (practically no lime) and a virtually complete absence of iron. "Ramlösa," in consequence, avoids the fault of certain natural mineral waters which upset the digestion by partially neutralising the hydrochloric acid in the gastric juice. "Ramlösa" considerably increases the amount of urine and is therefore indicated in the treatment of diabetes, gout, kidney troubles and other metabolic disorders, as well as in rheumatism and in conditions where a large supply of fluid is of importance as a mild form of irritant physical therapy.

WHOOPING COUGH

Detoxicated Whooping Cough Vaccine (Genatosan) has proved remarkably successful. Reports received from medical practitioners state that it usually reduces the frequency of the paroxysms after the first injection, and subsequent injections almost invariably clear up the condition. Owing to the elimination of the toxic elements of the germ during the process of manufacture, this vaccine may be given to infants and young children, in doses sufficiently large to produce the desired therapeutic effect, with an absence of harmful reaction.

The following is typical of many reports received from physicians:—

"I have been making a somewhat extensive use of your Detoxicated Vaccine for Whooping Cough, and am pleased to say that the results have been almost invariably gratifying. In nearly all my cases the very distressing symptoms have disappeared after the third injection." M.D.

Additional information regarding this Vaccine will gladly be supplied on request.

IRON

THE therapeutic value of iron is directly proportional to the ease with which ferrous ions are liberated. Recent experiments have shown the ferrous salts to be the most effective in the treatment of anæmias because they are more rapidly assimilated, require smaller doses and are more economical than other forms of iron now in use. An effective form of ferrous iron is available in 'Plastules' brand Hæmatinic Compound. Actual tests reveal that the absorption of ferrous iron in 'Plastules' is four to five times greater than that of ferric

ammonium citrate, 15 times greater than that of reduced iron, and is more readily adaptable to metabolism in the human body. Three 'Plastules' Plain provide the average patient with an adequate daily dose of iron to show a marked increase in hæmoglobin. . . . 'Plastules' provide ferrous iron and vitamins B₁ and B₂ in an edible oil in the form of a semi-fluid mass, enclosed in soluble gelatin capsules which quickly dissolve in the stomach. . . . 'Plastules' are available in two types—Plain and with Liver Extract.

Send for Samples and Literature.

Formula

Intestinal glands	-	0.05	grms.

Lactic ferments	-	0.05	"
Agar-agar	-	0.05	"
Fiat tablet	-	0.35	"

Initial Daily Dose
Two Tablets

Laxatives, it is well known nowadays, must have two essential characteristics.

1. They must be biological, i.e., they must accord with and imitate in their action the natural physiological processes of the intestine.
2. They must be capable of educating the intestine, so that the habit of a laxative is not formed and the intestine can function unaided when bowel adjustment is attained.

Taxol has both these advantages.

Taxol has not the violent irritant action of many laxatives and purgatives, but stimulates the intestine by processes which resemble those of nature. The intestinal gland which is an important part of its composition acts on the intestine by reinforcing the deficient function which has culminated in constipation. This stimulating action is gentle, and does not force the weakened intestine to efforts beyond its power, which would culminate in aggravation of the constipation.

Taxol is not habit-forming. It re-educates the intestine to resumption of normal function unaided, thanks to the biological nature of its action. It contains no irritant drug of violent and artificial action to which the intestine can become accustomed. On the contrary, many stubborn cases of constipation, after a course of *TAXOL*, revert to normal and regular peristalsis.

CONTINENTAL LABORATORIES LTD.

30 MARSHAM STREET, LONDON, E.C.4

"I would not have you take too much
Physick for it doth all ways make
me worse and I think it will do the
like with you."

This advice, given by a King in the 17th Century, is being repeated daily in a modern form by the medical profession who are well aware of the dangers of self-medication on the part of the public.

Purgation has been used from the dawn of history, but the modern method of treating constipation is by rational means and the avoidance of the ill effect of dehydration.

A rational method of treating constipation and allied intestinal disorders is afforded by 'Petrolagar,' which, mixing intimately with the contents of the bowels, forms a soft, easily moved faecal mass.

SEX HORMONE PREPARATIONS

GONAD STIMULATING HORMONES

ANTOSTAB

Prepared from pregnant mares' serum and contains the follicle stimulating hormone. Excellent clinical results have been obtained in the treatment of Amenorrhoea either alone or in conjunction with Physostab. (*Brit. Med. Jnl.* 1937, ii, 804) Supplied in boxes containing ampoules of 100 mouse units together with ampoules containing 1 c.c. of 0.90% Sodium Chloride Solution as a solvent. Single ampoules and boxes of 6 ampoules.

PHYSOSTAB

Prepared from human pregnancy urine and contains the luteinizing hormone. Of especial value during the second half of the menstrual cycle when it stimulates the production of corpora lutea. Excellent clinical results have been obtained in the treatment of metrorrhagia, undescended testicles and dystrophia adiposo-genitalis. Supplied in boxes containing ampoules of 100 mouse units, together with ampoules containing 1 c.c. of 0.90% Sodium Chloride Solution as a solvent for Physostab. Single ampoules and boxes of six ampoules.

OVARIAN HORMONES

OVOSTAB

An oily solution of ovarian hormone for intramuscular injection in the treatment of Amenorrhoea, the Menopause, Chronic Mastitis and cases of Ovarian Deficiency. Supplied in 1.1 c.c. ampoules containing 2,000, 10,000 and 50,000 International Benzoate Units per c.c. Single ampoules and boxes of six ampoules. Ovostab tablets (Oestrone) are available for oral use, 1,000 and 10,000 International Units per tablet. Bottles of 25.

LUTEOSTAB

An oily solution of the corpus luteum hormone for use in conjunction with Ovostab in treating Amenorrhoea and for the treatment of Abortion, Metrorrhagia and cases of Corpus Luteum Deficiency. Supplied in 1.1 c.c. ampoules containing 2 rabbit units per c.c. Single ampoules and boxes of six ampoules.

Prescribing a Laxative

When, as frequently happens, the Physician is called upon to prescribe a laxative for prolonged personal use by the patient, Andrews Liver Salt merits special consideration. The main characteristics of this tonic laxative, listed below, suggest its wide range of suitability.

- 1 Andrews is pleasant-tasting. All ages take it readily.
- 2 Andrews causes none of the griping or other discomforts which often create reluctance to continue the use of the more drastic purgatives. Its laxative action is due to the presence of magnesium sulphate and other salts, which increase the fluid content of the bowel by Osmotic action, and so lead to painless, easy evacuation.
- 3 Because of its natural and non-habit-forming action, Andrews—in suitable doses—may be taken with every confidence by the physically weak and during pregnancy. This tonic laxative does not affect adversely the secretion of milk in nursing mothers. Indeed, the quantity of water taken with Andrews Liver Salt contributes to the extra liquids a nursing mother should take.
- 4 Andrews is particularly valuable in the case of patients liable to digestive trouble. The carbon dioxide which is liberated when Andrews is dissolved in water has a soothing effect on the stomach and a physical cleansing action on the stomach walls. Additionally, Andrews corrects excess acidity, stimulates the liver and promotes the flow of bile.
- 5 Andrews creates no dependence on artificial aid, but can be discontinued when the need for it ceases.

X-ray reveals uniform density of Agarol.

... Agarol has had a physical examination

THE x-ray says: "Look for uniform density throughout as evidence of soundness". Agarol brand Compound is a thoroughly uniform emulsion that acts the same way with every dose.

The microscope says: "Look for the small uniform oil globules" as a sign of thorough emulsification of Agarol. It means stability, freedom from oiliness, ready miscibility with water, milk, fruit juices or any other liquid.

The microscope shows extremely fine division of oil in Agarol.

The pharmacist says: "If it pours freely, it is the sign of a good emulsion." Agarol is a good mineral oil emulsion that has thoroughly proved its value in the relief of acute constipation and in the treatment of habitual constipation.

Descriptive literature and a liberal supply of Agarol supplied gratis to Members of the Medical Profession on request.

Agarol is not advertised to the public

Agarol brand Compound is available 4½, 7½ and 17 ounce bottles.

The average adult dose is one tablespoonful.

Proctocaine is a lasting, non-toxic, local anæsthetic, for use in irritating or painful conditions of the skin and subcutaneous tissues. It is an improved form of A.B.A. Proctocaine is a combination of oil-soluble anæsthetics of low toxicity. These are combined so as to produce *immediate local anæsthesia* which is maintained by the slow, uniform absorption of its oily vehicle, and action of its oil-soluble ingredients.

The advantages of Proctocaine over other solutions have been found¹ to be as follows:

1. Its effect is almost certain.
2. It produces anæsthesia or hypo-anæsthesia for periods varying from 7 to 28 days or longer.
3. The relaxation which it produces in the anal musculature is much greater and more prolonged.
4. It is comparatively non-toxic, injection of 20 to 30 c.cm. producing no general effect.
5. Even large quantities of it at one sitting have not been found to produce any local reaction if injected properly.
6. Its injection is painless if made slowly.
7. In no case did it produce severe after-pain.

PREGNANCY AND LACTATION CHANGES IN FIBRO-ADENOMA OF THE BREAST*

BY

CHARLES F. GESCHICKTER, M.D., and DEAN LEWIS, M.D.
Baltimore, Maryland

(WITH SPECIAL PLATE)

The fibro-adenoma is the most common tumour of the breast occurring in young women in the child-bearing period. The firm character of the lesion, the definite encapsulation, and the slow growth over a period of years make the clinical diagnosis relatively easy. The rapid growth of fibro-adenoma during pregnancy and the cystic enlargement during lactation are less well-known features. These and the variety of microscopical changes which may be observed when the tumours respond to the hormonal influences of pregnancy and lactation may lead to some difficulties in diagnosis, and as a result mutilating operations may be performed needlessly.

Moran (1935) reviewed the literature on fibro-adenomas of the breast excised during pregnancy or lactation and the cases recorded to that date in the surgical pathological laboratory of the Johns Hopkins Hospital. He was able to find records in the literature of only nineteen cases verified by microscopical examination. The outstanding clinical features of the cases reviewed by this author were the definite enlargement of the growth during pregnancy or lactation, the history of the patient's awareness of the tumour for a period of two or more years before pregnancy, and the absence of changes in the overlying skin, in the nipple, or in the axilla during the period of rapid growth. Moran concluded that the changes produced in these growths by pregnancy and lactation were like those occurring simultaneously in the surrounding normal breast tissue and bore no relation to malignancy. He recommended that the growths be removed during pregnancy rather than during lactation if discovered in time, since the tumour before lactation is smaller, is less vascular, and is free from marked secretory activity.

The present study is based upon thirteen cases of fibro-adenomas removed during pregnancy, ten excised during lactation, and ten operated upon at varying intervals after the cessation of lactation. Every phase of pregnancy, lactation, and post-lactation involution is represented in this series. The study of the specimens permits a comparison of the microscopical changes in these tumours with those occurring simultaneously in the surrounding breast tissue. It likewise affords an opportunity for correlation of these changes with those produced experimentally in the breast of humans and other mammals by the injection of the various sex hormones.

* From the Laboratory of Surgical Pathology, Department of Surgery, Johns Hopkins Hospital and University.

Pregnancy Changes in Fibro-adenomas and in Normal Mammary Tissue

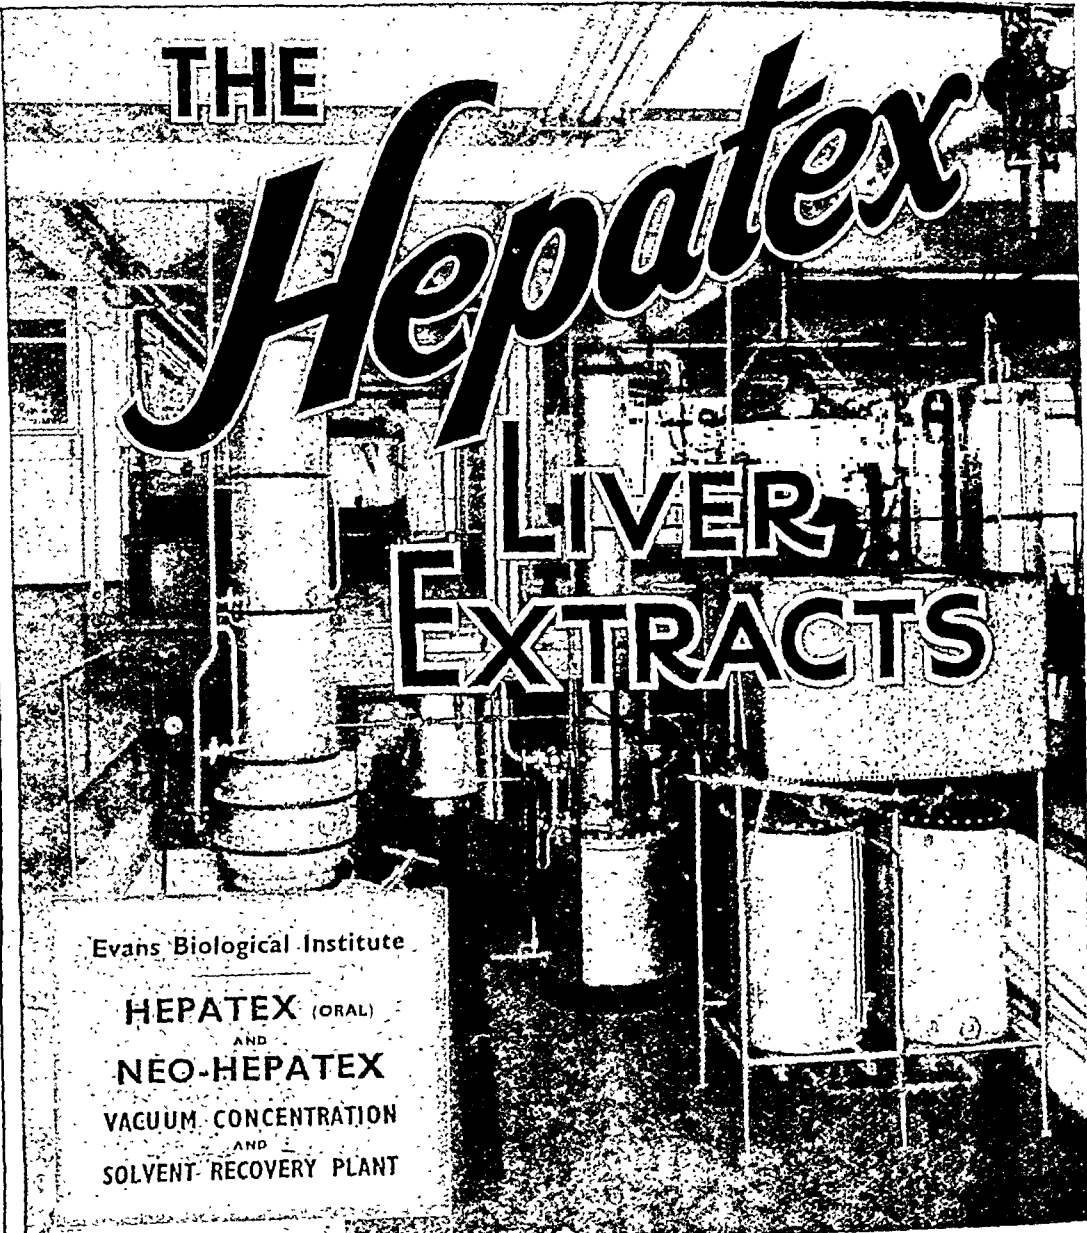

In the thirteen cases of fibro-adenomas removed during pregnancy all but one gave a history of rapid enlargement. In the case in which the patient had been unaware of any increase in size of the lesion the tumour was removed in the fourth month of pregnancy, but microscopically evidence of recent growth and of pregnancy was found. The tumour removed earliest in the course of gestation was excised in the fifth week. The nodule had doubled its size within four weeks. Two in which rapid enlargement was noted were removed in the sixth week and one at the end of the second month respectively. Nine out of thirteen were removed before the end of the first half of pregnancy (Table I). This corresponds to the period of

portion, as well as one near the nipple of the left breast. When examined in January, 1932, the lump in the upper portion of the right breast had definitely increased in size, and the tumour in the left breast had disappeared. The patient at this time was five and a half months pregnant. An excision of the tumour in the right breast was performed on January 5, 1932. The breast was vascular and the tumour was not encapsulated. Dr. Bloodgood made the note that "it cuts and scrapes like cancer, and on frozen section the cells are morphologically cancer," but it was decided not to do the complete operation because the changes were attributed to pregnancy rather than to malignancy. In February, 1932, post-operative irradiation was given because of the resemblance of the tumour to malignancy (Figs. 3, 4A, and 4B). In June, 1933, both breasts seemed normal on palpation, and there was no induration of the scar in the right breast. Soon after this

rounding breast tissue removed with these tumours the characteristic changes of late pregnancy are observed. The reduplicated terminal tubules are grouped into large lobules. Most of the periductal fibroblasts have disappeared and are replaced by capillaries engorged with red blood cells. The terminal tubules are dilated into acini, and many are lined by a single row of low cuboidal cells with secretion vacuoles. A few small nests of proliferating epithelial cells may still be seen, and also an occasional duct plugged with epithelial cells. Some acini are greatly dilated, suggesting the beginning of lactation.

The fibro-adenomatous tissue in this period presents interesting irregularities. Some of the tumour tissue

LEGENDS FOR THE SPECIAL PLATE

Fig. 1 (Case 13).—Bisected specimen of a fibro-adenoma removed at the beginning of the eighth month of pregnancy. The cut surface is fleshy and red in appearance. The tumour had not been noted before the beginning of pregnancy. Between the sixth week of gestation and the time of its removal the tumour had grown from a pea-sized nodule to a mass 9 cm. in diameter. The microscopical appearance of the tumour is shown in Figs. 5A and 5B.

Figs. 2A and 2B (Case 3).—Photomicrographs comparing A, normal breast tissue in the third month of pregnancy, with B, a growing fibro-adenoma removed from the same breast. The normal tissue (A) shows ramifying tubules surrounded by young connective tissue and numerous lymphocytes. A similar growth of tubules and connective tissue is seen in the tumour (B). The tumour tissue, however, shows a more marked proliferation of epithelium, some of which is forming small duct adenomas.

Fig. 3 (Case 10).—Gross specimen of a rapidly growing fibro-adenoma removed in the fifth month of pregnancy from a woman aged 29. The mass was not encapsulated, and on section cut like cancer.

Figs. 4A and 4B (Case 10).—Photomicrographs comparing A, normal breast tissue, with B, rapidly growing fibro-adenoma, both from the case shown in Fig. 3. The lobules of normal mammary tissue (A) contain large numbers of recently formed tubules. In some the remains of epithelial proliferation are seen. Others are dilated to form acini, which do not yet show secretory changes. The tumour tissue (B) shows proliferating masses of epithelium at the end of the mammary tubules. Under high power many of these cells have a malignant morphology. The epithelium is surrounded by rapidly growing connective tissue. The epithelium of the tumour invaded the surrounding fat. The patient died with metastases to the liver three years and ten months following the excision.

Figs. 5A and 5B (Case 13).—Photomicrographs of tissue obtained from the tumour shown in Fig. 1. The tumour was removed at the beginning of the eighth month of pregnancy. At A is shown the tendency for lobule formation with small cysts at the margin of the tumour and the absence of pregnancy changes in the more central portions: B shows another portion of the tumour in which the mammary lobules are in the pre-lactation state. The lobules are separated by large amounts of fibrous tissue.

Fig. 6 (Case 14).—Photomicrograph of a fibro-adenoma removed during the sixth week of lactation. The fibro-adenoma at the bottom shows lactation changes. The lobules,

however, contain a more dense supporting stroma and their acini are widely dilated. The normal lactating lobules in the surrounding breast tissue are shown above.

Fig. 7 (Case 17).—Gross specimen of a fibro-adenoma removed in the third month of lactation from a coloured girl aged 17. Milk exuded from the cut surface about the margins of the tumour.

Figs. 8A and 8B (Case 17).—Photomicrographs comparing A, normal lactating breast, with B, quiescent fibro-adenomatous tissue removed from the same patient. The gross specimen is illustrated in Fig. 7. At A is shown the normal lactating mammary tissue; B shows the quiescent lobules of the central portions of the fibro-adenoma surrounded by dense hyalinized connective tissue.

Fig. 9 (Case 15).—Photomicrograph showing subinvolution in a lactating fibro-adenoma. The tumour was excised from a coloured female, aged 36, who had had two pregnancies in successive years. She had been nursing the second child for six weeks at the time of excision. At A are shown the lactating lobules; at B are seen the fibro-adenomatous areas which have failed to lactate but are instead undergoing cystic change.

Figs. 10A and 10B (Case 20).—Gross specimen of a fibro-adenoma removed following nine months of lactation in a woman aged 34. The tumour grew rapidly in the first half of pregnancy and enlarged slowly thereafter. Its cut surface (10B) had the appearance of sarcoma.

Fig. 11.—Photomicrograph of the tissue removed from the margin of the tumour shown in Figs. 10A and 10B. Both the connective tissue and the epithelium show marked proliferation and resemble malignancy.

Fig. 12.—Whole mount of a female rat breast. The rat was castrated at 21 days and injected with 100 rat units (1,000 international units) of oestrone daily for 20 days thereafter. The dense epithelial buds seen on the ramifying tubules are the result of overstimulation with oestrone and do not occur if the rat is injected with doses up to 20 rat units daily for this period.

Fig. 13.—Photomicrograph of a female rat breast treated with 50 rat units of oestrone daily for 100 days following castration on the 32nd day. The dilated mammary tubules showed the remains of secretory activity and are lined by irregular epithelium, some of which is proliferating but most of which is atrophic. The outstanding feature is the amount of periductal connective tissue seen in the upper portion of the picture.

examination the patient again became pregnant. Towards the end of the second pregnancy two small tumours appeared in the region of the scar, but following the birth of the second child in February, 1934, one of them disappeared. In March, 1935, three years after the first operation, one small nodule remained in the region of the scar. This lump was stationary in size, and there was no enlargement of the axillary nodes. The patient complained of indigestion and the liver was enlarged. In October, 1935, the patient died with metastases to the liver, three years and ten months following the operation. No metastases were ever felt in the axillary nodes.

LAST THIRD OF PREGNANCY

The changes occurring in the last third of pregnancy are represented by three tumours, one removed during the sixth month, another during the seventh month, and the last at the beginning of the eighth month. In the sur-

rounding breast tissue removed with these tumours the characteristic changes of late pregnancy are observed. The reduplicated terminal tubules are grouped into large lobules. Most of the periductal fibroblasts have disappeared and are replaced by capillaries engorged with red blood cells. The terminal tubules are dilated into acini, and many are lined by a single row of low cuboidal cells with secretion vacuoles. A few small nests of proliferating epithelial cells may still be seen, and also an occasional duct plugged with epithelial cells. Some acini are greatly dilated, suggesting the beginning of lactation. The fibro-adenomas removed early in pregnancy, while in occasional areas pronounced epithelial proliferation with the formation of duct adenomas is found. In the fibro-adenoma removed just before the eighth month the changes of later pregnancy were observed at the periphery of the tumour, but only moderately increased growth of the connective tissue and of duct epithelium was noted in the central portions. The history and findings in this case are given below.

Case 13.—The patient is a white woman aged 22 who about six weeks after the onset of gestation noticed two small swellings in the lower half of the right breast, each slightly

The consistency of the tumours removed ranges from hard to rubbery firmness, and they were all freely movable without retraction of the nipple or dimpling of the skin. No enlargement of the axillary lymph nodes could be made out. In two instances (tumours removed at four and seven months) two tumours were found in the breast at operation. All the growths were apparently encapsulated. In spite of this and the absence of clinical signs of malignancy on inspection and palpation, malignancy was often suspected because of the rapid growth of the lesion and the firm nodular character. In the gross, six tumours showed macroscopic pregnancy changes. Five were observed to be granular on section, and one removed at the onset of the eighth month was soft and red (Plate, Fig. 1). Microscopically, marked epithelial proliferation, non-encapsulation at one or more points, with invasion of fat and many mitotic figures, were observed in the tumours removed during the first half of pregnancy. In these cases the infiltrating epithelium with mitotic figures may easily be mistaken for cancer by one unfamiliar with such pregnancy changes. In one instance cancer developed, and death from hepatic metastases occurred.

In general the microscopical changes occurring in fibro-adenomas during pregnancy correspond to those occurring in the surrounding normal breast tissue. The changes in the tumour, however, are more irregular—most pronounced at the margins—and there is a tendency for the tumour at first to exceed and later to lag behind the physiological development in the surrounding mammary tissue. Tumours of long standing with a considerable amount of hyalinization of the connective tissue may remain refractory to pregnancy changes, and those which have responded to a previous pregnancy may remain unchanged during subsequent gestations. Multiple fibro-adenomas in the same breast may show varying degrees of response. McFarland (1922) has reported a case in which the patient had three fibro-adenomas in the same breast removed during pregnancy. The largest tumour showed marked response, the medium-sized tumour showed some change, but practically no hypertrophy was observed in the smallest nodule.

FIRST THIRD OF PREGNANCY

The changes occurring in the first third of pregnancy are represented by seven tumours, one removed at the end of the first month, one at six weeks, another at the end of two months, and the remainder at the end of three months. The specimen removed earliest in pregnancy was a small fibro-adenoma excised at the end of the fifth week. The history of this case is given below.

Case 1.—The patient is a married woman aged 25. A small nodule had been present in the left breast for two years. At the first examination, October 1, 1936, a pea-sized nodule was palpated by her physician. On the second examination, one month later, the mass was twice this size and very painful. The lesion was excised on November 2, 1936. The diagnosis of cystic mastitis was made, pregnancy not having been suspected. The tissue and patient were then referred to us in order to rule out the possibility of malignancy and to investigate the cause of digestive upsets. From the tissue excised, and from the tense swollen aspect of the breast, a diagnosis of fibro-adenoma in pregnancy was made. The patient had missed one menstrual period. An Aschheim-Zondek test performed on December 1, 1936, was positive, and the baby was born on June 23, 1937. The nodule therefore was excised at the end of the fifth week of pregnancy. In the gross and microscopically the tumour was not encapsulated. It consisted of small branching tubules of rapidly dividing epithelium and proliferating fibroblasts. Lymphocytes were mingled with the fibroblasts.

The changes observed in this tumour and in those removed later in the first third of pregnancy are characterized by a progressively increasing, branching, and reduplicating of small terminal tubules (Figs. 2A and 2B), and a proliferation of young connective tissue about them. Some of these tubules extend into the adjacent neighbouring fat. The epithelium lining the ducts consists of small oval cells with scanty cytoplasm and dense nuclei, many of which are undergoing mitosis. In places these proliferating cells are without basement membrane, obliterate the lumen of the ducts, and grow into the ends of the adjoining ducts to form small duct adenomas. The fibroblasts surrounding the tubules show active growth and are interspersed with numerous lymphocytes. The number of budding tubules and the amounts of periductal connective tissue increase steadily until mid-pregnancy. The lymphocytic infiltration is greatest at the end of the second month, and diminishes in mid-pregnancy.

Microscopically all but one of the fibro-adenomas were non-encapsulated, showing irregular extension into the surrounding mammary parenchyma and fat. In the exception the tumour removed in the third month of pregnancy was definitely encapsulated and the stroma showed advanced myxomatous change. This tumour had remained relatively refractory to the changes of pregnancy. It measured $2\frac{1}{2}$ cm. in diameter, and had been first noted a year and a half previously, at the age of 27. It showed a moderate increase in the number of newly formed epithelial ramifications, and the pre-existing myxomatous stroma of the tumour was sprinkled with lymphocytes.

A comparison of changes in the fibro-adenoma with those in the surrounding breast tissue shows greater epithelial proliferation in the tubules and more rapid growth in the surrounding connective tissue in the fibro-adenoma. The lobules of the adjacent breast tissue are more heavily infiltrated by lymphocytes, and a larger number of terminal tubules remain patent, and are lined by only two or three rows of epithelium.

MID-THIRD OF PREGNANCY

The changes in the mid-third of pregnancy are represented by two tumours removed during the fourth month and one during the fifth month. The changes in the breast tissue during this period are transitional between those of the first and the last third. The newly formed tubules are grouped together in large lobules; the surrounding connective tissue is reduced in amount and is gradually crowded out. Lymphocytic infiltration is absent. The lumen of a few of the tubules shows dilatation, and occasional secretory vacuoles form in their lining cells. One of the fibro-adenomas removed in this stage was encapsulated and apparently quiescent. In another the growth of fibrous tissue continued, and in the third tumour there was progressive proliferation of both epithelium and connective tissue. In this case (reported below) malignant change occurred.

Case 10.—The patient was a white female aged 29 who had noticed a small lump in the breast two years previously. A surgeon who saw the lump eighteen months previously advised excision. On examination, May 23, 1931, a small nodule about the size of a 10-cent piece was palpated in the right breast in the mid-portion of the lower hemisphere. An indefinite swelling was felt in the upper hemisphere. Another small tumour was palpated above the nipple in the left breast. Both breasts were indefinitely lumpy to palpation. A diagnosis of lumpy painful breasts was made by Dr. Bloodgood; no operation was advised, and the patient was asked to return at monthly intervals. One month later examination showed no definite lump in the lower portion of the right breast, but a lump was still palpable in the upper

left breast, and an amputation was performed, April 9, 1898. The stroma was unusually cellular, and was differentiated with difficulty from sarcoma. The patient was reported well twenty-five years later.

Post-lactation Changes

Ten tumours excised at known intervals after lactation were chosen for study of the involutional changes. In four cases the tumour was excised within five months to a year after lactation, a fifth was excised at the end of fifteen months, and the remainder between two and eight years after the cessation of lactation. In three cases the tumour had been present in more than one pregnancy. The outstanding microscopical feature in these cases was the replacement by myxomatous and hyalinized connective tissue of the more cellular stroma found during pregnancy and occasionally persisting in lactation. Seven of the ten cases studied showed myxomatous changes. In one of the tumours removed two months after the cessation of

(Astwood, Geschickter, and Rausch, 1937). The histology of fibro-adenomas removed at puberty, characterized by growth of ducts and stroma without evidence of lobule formation, suggests that these neoplasms represent an increased response to oestrin on the part of the tissue involved. Oestrin, which is secreted by the ovarian follicle in increased amounts at puberty, acts as a stimulant to the growth of fibro-adenomas and accounts for their frequent appearance in patients at this period. The concentration of oestrin in the blood is again greatly increased during the first third of pregnancy (see chart). Growth of the fibro-adenoma as well as the surrounding breast results from this stimulation, and the ramification of mammary tubules and the increase in periductal fibrous tissue in both the tumour and the normal breast may be looked upon as a response to oestrin. Heiman and Krehbiel (1936) noted that oestrin in combination with anterior-

* UOQ=Upper Outer Quadrant; LIQ=Lower Inner Quadrant; UIQ=Upper Inner Quadrant.

lactation residual lactation was found as well as in the surrounding breast tissue. Less striking areas of residual lactation were seen in four of the other tumours. In several growths removed two or more years after the end of the nursing period strands of atypical proliferating epithelium were found at the margin of the tumour. In the majority, however, involutional changes such as occur in the normal breast were found. The epithelial tubules had collapsed, secretion was diminished or absent, and the lining cells had atrophied and were reduced to a single layer of quiescent epithelium. In one case in which the tumour was excised eight years after nursing an intermittent milky discharge from the nipple occurred. The excised fibro-adenoma was found to contain multiple cystic areas, some of which suggested residual lactation acini.

Discussion

Recent studies indicate that the changes observed in fibro-adenomas and in the surrounding breast during pregnancy and lactation are influenced by the sex hormones. The failure of the fibro-adenomatous tissue to respond to the same extent and in the same manner as normal breast tissue to all phases of pregnancy and lactation suggests that the tumour is more sensitive to certain hormones than to others.

The growth of mammary ducts and periductal fibrous tissue in both animals and humans is stimulated by oestrin

Chart showing the approximate amounts of hormones excreted in the urine during pregnancy. The curves for prolactin and oestrone are in mouse units per litre, and are average values obtained from pooled samples of urine used for the commercial extraction of these hormones. The curve of progesterone shown is based upon the recovery of the excretion product of progesterone—pregnandiol. The pregnandiol values may reach 90 mg. per litre in the last month of pregnancy, according to the studies of Browne, Henry, and Venning (1937).

pituitary-like hormones increased the number of spontaneous fibro-adenomas in rats and stimulated hyperplasia of duct and fibrous tissue in the normal breast. Since, in all but quiescent fibro-adenomas, the growth of the tumour is due to the continuous addition of newly formed tubules, response to pregnancy and lactation is to be expected in these units, which have not yet been pathologically modified through previous overstimulation. As the growth of the tumour is maximal at the periphery, the physiological changes of pregnancy and lactation are usually observed in these newly formed tubules at the periphery of the fibro-adenomas.

In recently developed fibro-adenomas or in more slowly growing tumours of longer duration oestrin stimulation in pregnancy results in marked increase in connective tissue and in pronounced epithelial proliferation. In one such case the stroma had the appearance of fibrosarcoma (Fig. 11). The atypical epithelial proliferation observed in these tumours can be reproduced in the rat breast with moderately large doses of oestrone (50 to 100 rat units daily) administered over a period of several weeks (Fig. 12). In these animals increased doses of oestrone, or moderate doses over longer periods of several months, result in cyst formation, followed ultimately by fibrosis (Fig. 13). Such cyst formation and fibrosis was observed in several tumours in this series (Cases 15 and 33).

larger than a pea. They increased rapidly in size in the next few weeks. By the fifth month of pregnancy they were as large as an orange, and the overlying skin became red and the veins enlarged. An attempt was made to drain this mass elsewhere, but no pus could be obtained. Examination revealed enlarged pendulous breasts, the right breast being nearly twice the size of the left. A mass approximately 9 cm. in diameter occupied the lower portion of the right breast. It was firm, freely movable, definitely encapsulated, and lobulated. Several drops of colostrum could be expressed from both nipples. The calculated duration of the pregnancy was slightly under eight months. Because of the size of the tumour a simple mastectomy was done on August 16, 1937. The tumour tissue was soft, fleshy, and red in the gross. Practically no secretion could be demonstrated. Microscopical study showed a typical fibro-adenoma with compressed epithelial channels. At the termination of these epithelial channels there were areas of hyperplasia. At the margins of the tumour irregular pregnancy changes were seen, corresponding to those in the surrounding breast tissue (Figs. 5A and 5B).

Changes During Lactation

The changes occurring in fibro-adenomas during lactation are represented by ten tumours, two of which were removed in the sixth week of lactation, three in the third month, one in the fifth month, and the remaining four towards the end of lactation, from the ninth through the twelfth month. As in pregnancy, changes similar to those in the surrounding breast tissue occur in parts of the tumour. However, with the exception of lobules scattered about the periphery the tumour tissue fails to respond to lactation. It shows a definite tendency to undergo involutional changes, the most characteristic features being hyalinization and myxomatous degeneration of the stroma. In some cases the rapid growth of connective tissue seen during pregnancy is continued into lactation. In the occasional lobules which show lactation changes the acini are more widely dilated than in the normal lactating breast, and the fibrous tissue in the dividing septa and in the papillary epithelial projections within the acini is greater in amount. Thus the lactating lobules within the fibro-adenoma are coarser in structure (Fig. 6). In the cases reviewed in this series there was apparently a greater tendency for lactation effects to appear in the fibro-adenoma in early lactation than in later lactation. The variety and irregularity of changes are greater in lactating fibro-adenomas than in those excised during pregnancy, because those occurring in pregnancy tend to persist and to have superimposed upon them, in isolated lobules, lactation changes. In the case detailed below the tumour was excised in the third month of lactation. As shown in Figs. 7, 8A, and 8B, the breast was the seat of typical lactation changes. The tumour for the most part remained quiescent, but irregular lactating lobules were scattered about the periphery. The outstanding effect was on the stroma of the tumour, which showed marked hyalinization.

Case 17.—The patient was a coloured girl, aged 17, who noticed a lump in her right breast two years previously. At this time it was about the size of a walnut. During the next year the tumour doubled in size, and thereafter remained stationary. The patient became pregnant in September, 1936. Soon after missing her first period she noted a rapid increase in the size of the tumour, which also became increasingly tender and painful. On examination both breasts were enlarged beyond the normal. The right breast was twice the size of the left and reached to the level of the umbilicus. A slight amount of serous discharge could be expressed from the left nipple. A nodular mass 17 cm. in diameter occupied the lower and central portion of the right breast. No enlarged nodes could be palpated in either axilla. The calculated duration of the

pregnancy was five and a half months. It was decided to postpone operation until after delivery. Caesarean section was performed on May 20, 1937, and the mass in the breast was removed on August 26 in the third month of lactation. The tumour in the gross was fleshy but definitely encapsulated. The cut surface was soft and bulging and exuded milk. Microscopical examination showed typical lactation changes in the normal breast tissue. The central portion of the tumour did not respond to lactation, but the periphery showed numerous secreting acini, many of which were cystic in appearance. The fibrous stroma was of the adult hyalinized variety, and some of the epithelium-lined channels showed the remains of proliferating activity while others showed atrophic changes.

In three of the tumours excised during lactation unusual effects were observed. In one (Case 15) the tumour which had appeared two years previously, was excised from a coloured female aged 36. There had been two pregnancies within the two years preceding operation. She had been nursing the second child for six weeks at the time of excision. The breast tissue showed characteristic lactation changes. In the tumour there were large cysts (Fig. 9). These were surrounded by areas of residual fibro-adenoma in which could be observed epithelial proliferation characteristic of the first half of pregnancy and some atypical lactating acini.

In the two remaining cases the unusual effects were presented by the stroma of the tumour, which resembled that of sarcoma.

A white woman, aged 34 (Case 20), had noticed a tumour fourteen months previously. The breasts were first examined following rapid growth of the mass during the fifth month of pregnancy. An encapsulated nodular tumour was found

which occupied the entire upper half of the left breast. With the onset of lactation the tumour ceased to grow. Following nine months of lactation the patient presented herself for examination in this clinic. At this time the tumour occupied practically the entire breast and was 16 cm. in diameter. The superficial veins were dilated and milk could be expressed from the nipple. The breast was amputated on September 27, 1927. On gross examination the appearance suggested sarcoma (Figs. 10A and 10B). On microscopical examination (Fig. 11) there was an extreme cellularity in the fibrous tissue which showed many mitotic figures. This was most marked at the margins of the tumour, and in these areas the epithelium of the terminal tubules looked malignant. The patient was reported well eight years after operation.

A tumour (Case 18) was removed from a woman aged 49, who had observed a tumour of the left breast for the third month of lactation. It had been painful and tender for eleven months. The tumour occupied nearly the entire

was very faintly positive. Two weeks later the boy's temperature and pulse rate had dropped to normal, he no longer had a cough, his weight had increased by 2 lb., no abnormal physical signs could be detected on examination of the chest, and a further x-ray film (Fig. 2) showed that the pulmonary condition had completely resolved. It might be suggested from a consideration of Fig. 1 and the positive Mantoux reaction that the correct diagnosis in this case should be epituberculosis, but the rapid resolution negatives this.

Case 2.—A girl aged 7 years, who had previously suffered from pertussis and measles, was brought to the out-patient department on January 21, 1937, on account of a cough, anorexia, and loss of weight of two weeks' duration. On examination her temperature was 99.2° F., her pulse 116, and respirations 24, and over the upper and middle zones of the left lung the percussion note was impaired, while on auscultation the breath sounds were vesicular and medium "sticky" rales were audible. The Mantoux reaction (1 in 1,000) was negative, and a white cell count showed a total of 11,800 cells per c.mm., the differential count being normal. A simple cough linctus was prescribed, and two weeks later the child was symptom-free, had gained 4 lb. in weight, and on examination of the chest no abnormal physical signs could be detected.

Case 3.—A boy aged 7 years, whose previous illnesses included measles and pertussis, was brought to the out-patient department on October 17, 1936, on account of a cough and anorexia of three weeks' duration. On examination he was afebrile, his pulse was 120 and respirations 24, and over the base of the right lung the percussion note was impaired, while on auscultation the breath sounds were vesicular and rales were audible. X-ray examination showed heavy shadowing in this area, together with some enlargement of the hilar glands. Two weeks later the boy was symptom-free, had gained 2 lb. in weight, and no abnormal physical signs could be detected in the chest.

Case 4.—A girl aged 6 years attended the out-patient department on October 12, 1935, on account of a lump in the neck. This was thought to be a tuberculous gland. The Mantoux reaction (1 in 1,000) was positive, and a radiograph of the chest showed calcified deposits in the hilar glands. The child was kept under observation, and gradually the cervical gland became smaller until finally it was no longer palpable. A year later, on October 14, 1936, she attended again, complaining of a cough of a few days' duration, and on examination an impaired percussion note was found over the base of the right lung, while on auscultation air entry was weak and "sticky" rales were audible. Her temperature was 99.4° F. A radiograph showed an opacity extending from the left hilar region outwards into the left mid-zone and a further opacity in the right lower zone. A few weeks later the cough had gone, the child had gained 3 lb. in weight, no abnormal physical signs were present on examination, and a second radiograph showed that the opacities previously noted had cleared. It might be suggested that these pulmonary lesions were tuberculous, but the appearances were not those of epituberculosis, and parenchymatous tuberculous lesions would not have resolved in such a manner.

Case 5.—A girl aged 9 years, whose previous illnesses included scarlet fever, pertussis, and mumps, was brought to the out-patient department on May 27, 1937, on account of cough, anorexia, and loss of weight of some three weeks' duration. On examination she was afebrile, her pulse 96 and respirations 20, and over the base of the left lung the percussion note was impaired, while on auscultation air entry was diminished and "sticky" rales were audible. She was given a simple cough linctus, and at her second attendance two weeks later she was symptom-free, had gained 2½ lb. in weight, and no abnormal physical signs could be detected in the chest.

DIFFERENTIAL DIAGNOSIS

1. The usual diagnosis made in these cases is that of unresolved pneumonia, and yet there is no history to suggest any recent pneumonia or other inflammatory pulmonary lesion. The condition cannot be one of long

standing, dating from some earlier illness, because the symptoms are recent in origin and resolution takes place within a week or two without treatment. For the same reasons simple pneumonitis should not be mistaken for the chronic pneumonias of infancy and childhood (Jaso and Fandos, 1934) or for subacute peribronchiolar pneumonia (Reichle and Moritz, 1934).

2. The comparative rapidity with which recovery takes place in simple pneumonitis, together with its benign course, renders differentiation fairly easy from most forms of tuberculosis of the respiratory system which are seen in childhood. Epituberculosis is sometimes more difficult to eliminate with certainty, but in this condition the Mantoux reaction is invariably positive, resolution is slow, and fever is usually absent (Moncrieff, 1934).

3. In a personal communication it has been suggested that simple pneumonitis is a form of allergic bronchopneumonia (Feingold, 1935), a condition seen in asthmatic children and thought to be due to allergic changes in the respiratory tract, producing bronchial obstruction, parenchymal infiltration, and fever. However, none of the cases of simple pneumonitis seen at the Middlesex Hospital have had any allergic manifestations, either respiratory or systemic, nor is there any evidence of familial allergic phenomena. In order to show how allergic bronchopneumonia differs from simple pneumonitis a case of the former is included in this series.

Case 6.—A boy aged 5 years was brought to the out-patient department on May 6, 1937, on account of bronchial asthma, from which he had suffered since the age of 6 months. There was a strong family history of allergy on the maternal side. On examination of the chest there was much bronchial spasm. He was afebrile, his pulse 112 and respirations 24. X-ray examination (Fig. 3) showed enlargement of the hilar glands, thickening of the septum between the upper and middle lobes of the right lung, and shadowing in the left cardio-phrenic angle. It was found that the boy slept on feather pillows and that there was a down coverlet on the bed. These articles were removed from the bedroom and the patient was given a mixture containing potassium iodide and stramonium. He began to improve, the physical signs in the chest disappeared, and further radiographs one month later showed that the shadowing in the left cardio-phrenic angle had cleared. The hilar shadows were smaller and the interlobar septum was no longer visible.

CASES IN ADOLESCENTS

Case 7.—A youth aged 17 attended the out-patient department on April 1, 1937, complaining of a cough, blood-stained

FIG. A.—Temperature, pulse, and respiration charts of Case 7.

expectoration, loss of weight, and anorexia, the symptoms being of three days' duration. He denied any previous illnesses, and stated that there was no tuberculosis in his family. On examination his temperature was 99.4° F., pulse 96, respirations 20, and at the left base the percussion note was impaired, air entry was weak, and rales were audible. X-ray examination (Plate, Fig. 4) showed enlargement of the hilar glands, together with a dense opacity in the left lower

Advanced fibrosis with hyalinization or myxomatous change in the stroma in fibro-adenoma of long standing or in tumours with an unusual intensity of oestrogenic response accounts for those fibro-adenomas which remain refractory to the hormonal influences of pregnancy and lactation. The fibrosis characteristic of these quiescent lesions is simulated experimentally by fibrosis in the mammary gland of the rat produced by overstimulation with high doses of oestrone (50 rat units daily) given over a period of 100 days (Fig. 13). The amount of fibrosis thus obtained in the rat's breast is remarkable in view of the small amount of connective tissue in this organ under normal condition.

On the basis of the above considerations oestrin stimulation, direct or indirect, may be looked upon as the most important factor in the wide variety of changes in fibro-adenomas observed during pregnancy and lactation. The multiplication of mammary tubules and periductal connective tissue seen in the first third of pregnancy is a direct effect of oestrin. These newly developed tubules in late pregnancy are acted upon by other hormones, leading to the formation of acini and development of lactation. Atypical epithelial proliferation in the mammary tumour similar to that seen in Schimmelbusch's disease or adenosis and cyst formation are pathological effects resulting from oestrogenic overdosage, and can be reproduced experimentally in the rat's breast by repeated oestrone injections. Fibrosis such as is seen in those tumours which remain quiescent is the result of prolonged and intense response to oestrin. Involution and secretion with cyst formation in these tumours may be stimulated by the lactogenic hormone of the anterior lobe of the pituitary gland. In general, the effect of the lactogenic hormone seems to hasten and make more marked involutional changes.

The report of the Gordon Memorial College, Khartum (1936), reflects the beginning of the emergence of the Sudan from the world-wide wave of financial and economic depression. After a continuous decrease in the number of pupils, following the peak year of 1930, the turning point now appears to have been reached, and 1937 opens with 325 pupils, an increase of thirty-four over the figure of the previous year. An interesting analysis of the parentage, nationality, and provinces of origin of the pupils shows that a large proportion are sons of officials, of Arab nationality, and from the province of Khartum. The report states, however, that the son of the Government official is generally less endowed with brains than the offspring of the illiterate peasant of the provinces or of the townsman following some very humble trade or calling. With regard to the subsequent employment of pupils of the college, the lean time of the depression has been succeeded by an extremely satisfactory state of affairs, and it is anticipated that in the course of the next few years the supply will not be equal to the demand. According to figures given for pupils who completed their full four years' course at the end of 1935 and 1936 respectively, the majority appear to secure appointments in permanent Government service. Of ten pupils from the scientific section in 1936, nine entered the Kitchener School of Medicine.

PNEUMONITIS

BY

A. MORTON GILL, M.D., M.R.C.P.

Medical Registrar, Middlesex Hospital

(WITH SPECIAL PLATE)

The rapid advance of radiological technique in recent years has enabled the clinician to gain a clearer conception of the nature of many pulmonary conditions, some mild, some serious, the physical signs of which are so similar as to render differentiation by clinical methods alone exceedingly difficult, if not impossible. Among the most important of these conditions is one which American authors and, more recently, English workers have termed *pneumonitis*. By definition this name signifies an inflammatory pulmonary reaction. It is evident that the aetiology of such an inflammatory reaction is likely to be varied, and it is the purpose of this paper to present a practical classification of the condition. The following varieties of *pneumonitis* have been described: (1) acute simple; (2) secondary types; (3) chronic.

1. Acute Simple Pneumonitis

In a recent paper I gave an account of this disease as seen in children (Gill, 1937). Since then annotations have appeared in the *Lancet* (1937) and the *British Medical Journal* (1937), while Beaumont (1937) and Moncreff (1937) now recognize the condition as a separate entity. After an intensive search through the literature one other account has been found which, under the heading of acute *pneumonitis* (Allen, 1936), undoubtedly refers to the condition here described.

Briefly, a child is brought to hospital for a cough of recent origin, anorexia, and loss of weight. There may be blood-stained expectoration, and the mother is sometimes suspicious of phthisis. The child is listless, the temperature is normal or slightly raised, the respiration rate is normal, and tachycardia is present. Examination of the chest reveals one or more areas over which the percussion note is slightly impaired, while on auscultation the breath sounds are normal or weak vesicular, and persistent medium "sticky" rales are audible. An x-ray examination reveals opacities in the zones under suspicion. Some enlargement of the hilar glands may be present. The white cell count is either within normal limits or is slightly increased. The erythrocyte sedimentation rate is raised. No treatment is necessary, and within a week or two the symptoms, signs, and radiographic changes completely disappear, the child's general condition improves, and he proceeds to regain his lost weight. Several cases have now been seen in adolescents and in adults, and examples of these, together with a further small series of cases in children, are described below.

CASES IN CHILDREN

Case 1.—A boy aged 4 years was brought to the out-patient department on April 1, 1937, on account of a cough and loss of weight amounting to 1 lb. over a period of two weeks. At the age of 1 year he had had pneumonia with bilateral otitis media, and subsequently, in fairly quick succession, measles, scarlet fever, and chicken-pox. He had undergone tonsillectomy two months previously. On examination the temperature was 100° F., the pulse rate 120, and respirations 20, and over the middle and lower zones of the lungs the percussion note was impaired, while on auscultation the breath sounds were vesicular and showers of "sticky" rales were audible. X-ray examination (Plate, Fig. 1) showed an opacity in this region, and a leucocyte count revealed a total of 13,200 cells per c.mm., of which 74 per cent. were neutrophils. The Mantoux tuberculin reaction (1 in 1,000)

2. Secondary Types of Pneumonitis

Several varieties of pneumonitis have been described, occurring as a secondary manifestation in some other disease.

(a) *Acute Influenzal Pneumonitis* (Bowen, 1935).—Some two to three days after the usual explosive onset of influenza the patient develops a cough, and on examination of the chest an area is found over which the percussion note is impaired, while on auscultation rales are audible. The respiration rate remains normal and the patient's general condition good, in contrast to those who are afflicted with influenzal pneumonia (Boyd, 1935) who are toxic, prostrate, and cyanosed, the wings of death beating ever nearer. The following is an example of the clinical and radiological changes that occur in acute influenzal pneumonitis.

Case 12.—A man aged 28 was suddenly taken ill on April 25, 1937, with headache, shivering, dizziness, malaise, and fever. These symptoms persisted and were followed three days later by cough and expectoration. On admission to hospital his temperature was 100.6° F., pulse 92 and respirations 18. No abnormal physical signs were detected on examination. An x-ray film of the chest, however, showed (Fig. 9) an opacity in the right middle and lower zones, together with enlargement of the right hilar glands. A white cell count revealed a total of 16,000 cells per c.mm., of which 10,400 were neutrophils. On May 3 an area of dullness was found over the base of the right lung. The breath sounds in this region were vesicular and were accompanied by medium rales. The temperature and pulse settled to normal, the patient became symptom-free, and a further x-ray film on May 8 showed that the pulmonary condition was resolving, and by May 19, when he was discharged from hospital, the abnormal physical signs in the chest had cleared.

There is, of course, no proof that the above patient had influenza. However, he was taken ill during an influenza epidemic; other patients, suffering from influenzal pneumonia and lying in the same ward, offered a strikingly different clinical picture; and, finally, the symptoms—namely, headache, shivering, dizziness, and malaise—are in strict accord with those which have been laid down by Stuart-Harris (1937), one of the band of workers, comprising Andrewes, Laidlaw, and Smith, who have recently elucidated the problem of epidemic influenza. Indeed, Stuart-Harris in his paper gives a brief account of influenzal pneumonitis, and considers that the condition is a "bronchiolitis with patchy atelectasis." From such cases he was able to isolate the virus.

(b) *In Association with Pulmonary Abscess.*—Beaumont (1937) states that a pneumonitis may be the first lesion that develops in an area of lung before liquefaction occurs with cavity formation. Bowen (1935) and Beaumont (1937) use the term "pneumonitis" to describe the exudative inflammation that is so often seen around a lung abscess.

(c) *In Association with Bronchiectasis.*—All those physicians who are interested in respiratory diseases are familiar with the patient, a sufferer from long-standing bronchiectasis, who from time to time develops an acute exacerbation of his symptoms, with fever, lasting perhaps for two or three weeks and gradually settling at the end of this time. During this period the abnormal physical signs already present are increased, while radiographs reveal opacities extending from the bronchiectatic areas into normal lung. With defervescence of the fever the symptoms and physical signs return to their former degree, and further radiographs show resolution of the inflammatory areas. Such a process is admirably and concisely described as a pneumonitis.

(d) *In Association with Other Pulmonary Lesions.*—A similar process to that just described under bronchiectasis may be seen in connexion with bronchial neoplasms, pulmonary emboli, and pulmonary collapse (Beaumont, 1937).

(e) *In Association with Vincent's Infection.*—Cahan (1927) and Davis and Harper (1931) have reported cases in which, during the course of a Vincent's angina, the physical signs and radiological appearances of a pneumonitis have developed in one or more pulmonary areas. These lesions have resolved after the exhibition of arsenicals.

(f) *In Association with Rheumatism.*—Klein (1934) reports the case of a little girl suffering from chorea and rheumatic carditis complicated by pneumonia. On somewhat scanty evidence he concludes that the latter condition is a rheumatic manifestation.

3. Chronic Pneumonitis

Cases of chronic pneumonitis are reported in the literature from time to time (Colton, 1927; and Cabot Case 20092, 1934). It would appear that the essential lesion is a progressive pulmonary fibrosis of unknown aetiology. Some of these patients eventually develop pure right heart failure, which may prove fatal.

Summary

1. An account is given of pneumonitis, a term used to describe a recently recognized type of inflammatory pulmonary reaction.

2. Pneumonitis is divided primarily into three main groups—acute simple pneumonitis, secondary types of pneumonitis, and chronic pneumonitis.

3. Examples are given of acute simple pneumonitis as it occurs in children, adolescents, and adults.

4. Secondary types of pneumonitis include acute influenzal pneumonitis and pneumonitis in association with pulmonary abscess, bronchiectasis, bronchial neoplasms, pulmonary collapse, pulmonary embolism, Vincent's angina, and possibly rheumatism.

Dr. G. E. Beaumont has given me invaluable help and criticism in the preparation of this article. I am indebted to Dr. C. E. Lakin, Dr. T. Izod Bennett, and Dr. Alan Moncrieff for permission to publish cases under their care; to Professor James McIntosh for the white cell counts; and to Dr. Graham Hodgson for permission to reproduce the x-ray films.

zone. It was thought that the condition was probably one of basal tuberculosis, and he was admitted to hospital. However, examination of the sputum on three occasions failed to reveal the presence of tubercle bacilli, his temperature and pulse rate gradually settled (Fig. A), the blood sedimentation rate (Fig. B), which was raised, also dropped to normal, the abnormal

FIG. B.—Case 7: Blood sedimentation rates (Westergren).

physical signs in the chest gradually disappeared, and a further radiograph (Fig. 5) showed complete resolution of the pulmonary condition. He was discharged from hospital on April 30, 1937, afebrile and symptom-free, having gained 8 lb. in weight.

Case 8.—A youth aged 16 attended the out-patient department on May 3, 1937, complaining of a cough, expectoration, lassitude, and loss of weight. His symptoms were of two weeks' duration. Apart from an operation for acute appendicitis in 1934 he had had no illnesses in the past. There was no tuberculosis in the family. On examination his temperature was 98.6° F., pulse 96 and respirations 20, and over the base of the left lung the percussion note was impaired, air entry was weak, and medium rales were audible. The blood sedimentation rate was 22 mm. (Westergren), and a white cell count showed 6,200 cells per c.mm., the differential count being normal. No treatment was prescribed, and a week later the boy was symptom-free, had gained 2 lb. in weight, and no abnormal physical signs could be detected on examination of the lungs. He remains well, and his Mantoux reaction (1 in 1,000) is negative.

CASES IN ADULTS

Case 9.—A man aged 32 attended the out-patient department on December 17, 1936, complaining of a cough with slight expectoration of one week's duration. The sputum had been streaked with blood on one occasion. He had had no serious illnesses in the past. On examination of the chest the percussion note was impaired at the right base, breath sounds were vesicular, and persistent "sticky" rales were audible. An x-ray film showed an opacity in this region. The sputum was negative for tubercle bacilli. He was seen again one week later, when he complained, in addition, of pain in the right chest. The physical signs remained unaltered. He was sent home to bed for ten days, and at the end of this time confessed that he felt perfectly well. No abnormal physical signs could be detected in the chest, and a further radiograph showed that the opacity previously noted had cleared.

Case 10.—A man aged 60 came to the out-patient department on January 28, 1937, complaining of a cough, expectoration, and loss of weight of two weeks' duration. He stated that he had never had a day's illness up to this time. On examination he was pale and thin, and over the middle and lower zones of the right lung the percussion note was impaired, while on auscultation the breath sounds were vesicular and rales were audible in this area. He was afebrile, his pulse was 96 and respirations 20. X-ray examination (Fig. 6) revealed shadowing in the region under suspicion, and it was thought that this was a case of pulmonary fibrosis. A fortnight later, however, he was symptom-free, had gained weight, and no abnormal physical signs could be detected on examination of the chest. Further radiographs were taken, and the shadowing previously noted had almost entirely cleared. At the present time he is well and his Mantoux reaction (1 in 1,000) is faintly positive.

Case 11.—A man aged 26 was taken ill with malaise, cough, and expectoration on March 24, 1937. He was found to be febrile and to have a tachycardia, but there was no increase

in the respiration rate. No abnormal physical signs could be detected on examination. The fever gradually settled, the tachycardia diminished, and the symptoms cleared, so that by April 6 the patient was well enough to be allowed up. As a precautionary measure an x-ray film was taken of the chest, and this (Fig. 7) showed mottling and increased striation in the upper zone of the right lung, the appearances being highly suggestive of pulmonary tuberculosis. However, in view of the patient's general well-being, it was decided to wait for three weeks and then repeat the x-ray examination. This (Fig. 8) showed that the pulmonary condition had completely resolved. Since this date the patient has remained in normal health.

DIFFERENTIAL DIAGNOSIS

Little need be added here to that which has already been said under the differential diagnosis of simple pneumonitis in childhood.

1. Recent pneumonia, unresolved pneumonia, and chronic pneumonia are readily differentiated for the reasons given above.

2. Disseminated focal pneumonia (Scadding, 1937) differs from acute simple pneumonitis in its initial symptoms, in the expectoration of purulent sputum, and in pursuing a more prolonged course with delayed resolution. Scadding suggests that disseminated focal pneumonia may be an earlier phase of the condition he has already described under the heading of chronic diffuse bronchopneumonia (Scadding, 1936).

3. As is well known, the majority of adult town-dwellers in this country have been infected by the tubercle bacillus: this primary infection in most cases leaves a healed focus somewhere in the body, but some of these people do not thereby acquire complete immunity, and proceed sooner or later to develop some form of phthisis. This stage of tuberculous pulmonary infection is called by Wingfield (1937) the "secondary" or "S" lesion. He states that the lesion consists of a central core of tubercle bacilli surrounded by a zone of allergic reaction, and, further, that if the deposit of bacilli is small enough and the host's immunity sufficiently high the whole lesion may disappear completely, leaving no trace. For this attractive theory no definite proof is offered, and, moreover, this teaching is contrary to the generally accepted view—namely, that pulmonary lesions containing tubercle bacilli heal by fibrosis, leaving scar tissue which can readily be detected by x-ray examination. Furthermore, those tuberculous pulmonary lesions, believed to be allergic, which occur in childhood invariably leave recognizable foci on healing—for example, Ghon lesions.

For these reasons, and also because several of the cases exhibited a negative Mantoux reaction, it seems evident that acute simple pneumonitis is not a manifestation of tuberculous infection of the lung.

PATHOLOGY

Since no fatalities have as yet been recorded in acute simple pneumonitis it is impossible to do more than conjecture as to the exact pathological process underlying the clinical and radiological picture constituting this condition. It was originally suggested (Gill, 1937) that the primary lesion may be a low-grade inflammatory process chiefly affecting the pulmonary alveoli. In a personal communication Beaumont has since pointed out that the same syndrome could be produced by partial obstruction of one or more bronchioles by a muco-purulent inflammatory exudate. The presence of blood-stained sputum in several cases suggests that the condition is either bronchiolar or alveolar, and not primarily a reaction of the interalveolar tissues. In the state of our knowledge further discussion, necessarily theoretical, would be sterile.

We know, further, that cancer cells may remain latent, presumably encapsulated by a fibrous tissue reaction. This is the only possible explanation of the late recurrences sometimes seen. I would instance a patient whom I saw recently who had a radical removal of the breast done for carcinoma, and who came up twenty years later for a recurrence in the lumbar spine. In this particular case it is certain that the deposit was there at the time of the operation. I am suggesting that operation, by cutting down the amount of cancer present, allows it to be successfully dealt with and shut off. Then at a later stage some other factor comes into play, possibly trauma, possibly a lowering of the general health of the patient, and the cancer cells resume their interrupted activity.

I do not wish to imply that partial operations should be undertaken, or that radical removals of a primary source should be done in the presence of gross secondary deposits. I am only placing this case on record to show that a patient who might have been regarded as hopelessly inoperable is still alive and well after an interval of ten years.

Summary

A case of carcinoma of the descending colon associated with a nodule in the liver is reported in which the patient is alive and well ten years after a partial colectomy.

THE PLANTAR WART

VERRUCA PLANTARIS: VERRUCA PEDIS: PLANTAR PAPILLOMA

BY

R. M. B. MacKENNA, M.A., M.D., M.R.C.P.

Honorary Dermatologist, Royal Southern Hospital, Liverpool

(WITH SPECIAL PLATE)

At the present time there is a widespread epidemic of plantar warts among school children. So far as my experience goes the epidemic is most severe among adolescent girls, although I have seen several boys whose ages ranged from 8 to 17 years suffering from the complaint. In South-West Lancashire the epidemic scarcely affects the so-called hospital classes, and the majority of cases are in children who attend boarding-schools; it would seem to be unduly optimistic to believe that all classes of the community will not be soon infected. Until recent years this type of wart has not been prevalent, and it is difficult to discover why the present epidemic has developed.

Plantar warts (or "verrucae," as they are called by many patients and some chiroprudists) are a minor malady, but when they have reached an average size they considerably curtail the activities of the person affected, owing to the pain caused by pressure on the warts whenever he attempts to walk or run. The warts develop insidiously. The first sign is the formation of a small semi-translucent macule, 1 to 2 mm. in diameter. There are no signs of inflammation. The macule is slightly painful on pressure, but is usually disregarded by the patient, who, if he considers the matter at all, believes that he has a tiny piece of grit embedded in the sole of his foot. The lesion, as a rule, develops on the heel or the ball of the foot, but may appear on any part of the plantar surface,

including the toes. The macule increases slowly in size until it reaches a diameter of approximately 0.5 cm., when the wart may be regarded as being fully formed. On examination one finds a roughened, hyperkeratotic type of lesion, greyish yellow in colour, and its papillomatous nature is usually, not apparent until the wart is pared with a knife. Satellite warts develop, and it is not uncommon to find as many as ten warts on one foot. The subjective symptoms vary with the site of the warts and the stoicism of the patient. One can generally obtain a history of throbbing pain, which is most severe when the patient gets out of bed in the morning or when he puts on his boots and starts to walk. The pain usually diminishes after he has been standing for some little time. He may complain that the warts throb when he has a hot bath.

Plantar warts have to be differentiated from callosities due to pressure: but medical men are so accustomed to recognizing callosities due, for example, to dropping of the anterior arch of the foot or to faulty shoes that the differential diagnosis is not often a matter of difficulty. In a doubtful case one should remember that whereas little or no pain is experienced when a callosity is pressed, the patient always complains of severe pain if a plantar wart is treated similarly: further, if the lesion is pared down the papillomatous nature of the wart becomes apparent.

Aetiology and Pathology

There is little doubt that plantar warts are caused by a filter-passing virus. It is probable that individual susceptibility to this virus varies considerably, but the virus is virulent and appears to be able to obtain a secure foothold on skin which to the naked eye reveals no sign of abrasion. Whilst the virus probably cannot develop or multiply except on a medium of living cells, it is reasonable to presume that it can remain alive for some minutes, if not for a few hours, on areas where an affected foot has pressed. If the superficial layers of a wart are shaved off the closely packed papillae are revealed. The papillae are in most cases yellowish white in colour, but may be stippled with red or brownish stains where haemorrhage has occurred. They are encircled by a tough horny collar. The lesion is broader at its base than at the opening on the surface of the skin.

The histology has been described by MacLeod (1933) in the following terms: "Microscopical sections show hyperkeratosis at the periphery, and marked acanthosis and elongation of the interpapillary processes in the centre. Towards the centre of the processes the prickle cells tend to be vacuolated." Inclusion bodies may be found in these vacuolated prickle cells.

Treatment

Treatment must be divided into two categories, preventive and active. In my opinion preventive treatment is of the utmost importance at the present time, and I would urge that all doctors who are in charge of schools should institute regular inspection of their pupils' feet, at least until the present epidemic has passed. School children suffering from plantar warts should be segregated so far as dormitory accommodation is concerned. They should have their own bathrooms and changing-rooms, and should not be permitted to use the school swimming-bath. Special care should be taken that their boot lockers are far removed from their colleagues', whilst the bootblack should have instructions always to clean the patients' boots in a batch after he has finished with those belonging to the rest of the school.

SPONTANEOUS DISAPPEARANCE OF
CARCINOMA

BY

DIGBY CHAMBERLAIN, Ch.M., F.R.C.S.

*Surgeon with Charge of Out-patients, General Infirmary at
Leeds*

(WITH SPECIAL PLATE) -

It has long been recognized that carcinoma of the large intestine is a very slow-growing form of malignant disease, and it is being realized now that its rate of growth is probably even slower than we had previously thought. It is not until some degree of obstruction begins to make its appearance that our advice is sought, and if we go carefully into the history we may find evidence of some indefinite abdominal symptoms which may go back for as long as two or three years. Even when the disease has been present for this length of time the outlook is comparatively favourable if the acute obstructive condition is relieved and the growth subsequently removed. When we open the abdomen in these cases we usually find a comparatively small primary lesion, with some enlargement of the glands in the mesocolon. It is only in the later cases that we find involvement of the aortic glands or secondary deposits in the pelvis with free fluid. Secondary nodules in the liver are also, as a rule, a late phenomenon. The latter two forms of extension are usually regarded as contraindicating any form of radical surgery.

Case History

A man aged 41 was seen on March 29, 1927, when he gave a history of attacks of pain in the left side of the abdomen for some considerable time. These had been diagnosed as due to renal colic, and he was eventually x-rayed, with negative results, in December, 1926. Colicky abdominal pain and increasing constipation began to be felt four weeks before he came up for treatment. For ten days he had noticed his abdomen becoming fuller, and he had commenced to vomit. At the time of his admission he had absolute constipation. He was obviously suffering from acute intestinal obstruction, and as he gave no response to enemata his abdomen was opened by a right paramedian incision. A growth was found in the descending colon, and the gut above it was very much distended. His caecum was brought out through a separate incision in the right iliac fossa and a Paul's tube tied into it. Three weeks later his abdomen was reopened by a left paramedian incision and examined in more detail. The distension of the gut was considerably less. One or two of the paracolic glands were enlarged, and on sweeping the hand over the convex surface of the right lobe of the liver a nodule which was hard and about the size of a pea was felt on its surface. This was taken to be a secondary deposit and seemed to exclude any hope of resecting the growth. It was felt undesirable to leave the patient with a caecostomy on account of the difficulty of controlling a liquid discharge, and the choice lay between a short circuit and a partial colectomy. The left half of the colon was mobilized and a piece stretching from the left side of the transverse to the upper part of the sigmoid colon was removed. The two ends were closed and continuity was restored by a side-to-side anastomosis.

The pathological report on the specimen read as follows: "The growth is a typical adenocarcinoma, showing some mucoid degeneration in parts. It almost encircles the gut, causing some narrowing. Melanosis is present above the growth." Two photomicrographs are here reproduced (see Plate).

Following the operation his caecostomy opening gradually got smaller and he was discharged with it practically closed five weeks later. For about eighteen months he was seen

periodically because of some leaking from it, and it then appeared to close finally. During this time his general health improved and no sign of any further growth was seen. He went to Ireland for business reasons at this time and nothing more was seen of him until February, 1937, when he came up with a history of three weeks' constipation. His general health had been good for the ten years since his operation. He had been so well that his business affairs had prospered; but he was worried, as he knew that a growth had been removed and he was afraid of a recurrence. There was still no sign of a return of the growth, and a barium enema showed a colon, with no sign of any obstruction, in which it was practically impossible to tell that a resection had been done. He was reassured, and has now returned to his work.

Discussion

The interest in this case centres on the nature of the nodule that was felt in the liver. The obvious diagnosis was of a secondary carcinomatous nodule, but there was no verification of this with absolute certainty. Simple liver tumours occur occasionally and are usually accidental findings at a post-mortem examination, so that there is no reason why they should not be accidental findings during the course of an operation for some other condition. We are thus left with the two alternative diagnoses of a secondary deposit and a simple tumour such as a bile-duct adenoma. Except for the subsequent history the former of these would appear to be the more likely.

There is no doubt that carcinoma can and does disappear spontaneously, as instanced most strikingly in Pearce Gould's (1910) classical case. Further, we know that cancer cells which are carried to the liver and the lungs are often destroyed and that they do not always give rise to metastatic growths. Teacher (1908), in an article on the development and natural healing of secondary tumours of chorion-epithelioma malignum, brings forward evidence to show that haemorrhage and thrombosis in a tumour are able to destroy the tumour cells, and that healing is brought about by a process of encapsulation within a zone of actively growing connective tissue and blood vessels which invade the tumour nodule.

It is said that in tuberculosis when there are two foci of disease the elimination of one may allow the natural defence mechanisms to overcome the other, whereas the two together might be progressive and beyond the patient's power to deal with. May it not be that a similar state of affairs holds in cancer and that the question of dosage is an important one? It is possible that cancer cells may be left behind after radical operations, and that we may congratulate ourselves on having removed the disease in its entirety when it is really the natural resistance of the body that has made our efforts successful.

It is usually held that the presence of one growth protects its host from the development of another, probably on account of the elaboration of some antibody which makes its way into the circulating blood. Thus in the tar warts which are produced in the experimental animal only one of them becomes malignant, and in polyposis of the colon, which is well known to be pre-cancerous, only one polypus shows a malignant change. The removal of the carcinoma in such a case may be followed at a later date by the appearance of a malignant change in one of the other polypi or warts. The two cases are, however, hardly parallel. Here we are dealing with an actual growth and a potential one, whereas in the case I am reporting there were two established foci, one certain and the other probable.

than that of cerebrospinal fluid. It can be demonstrated *in vitro*, by using alcohol coloured with a dye, that it floats on the surface of cerebrospinal fluid for several minutes with very little admixture. It is therefore possible, by placing the subject in a suitable position, to introduce alcohol into the subarachnoid space in such a way as to cause it to come into contact with the posterior roots it is intended to destroy, but not with other structures which it would be undesirable to injure.

Dogliotti himself in his original paper described forty-five cases of various kinds (all non-malignant) treated in this way with doses ranging from 0.2 to 0.8 c.cm. Of these patients twenty-seven (60 per cent.) were partially relieved, and nine (20 per cent.) were unrelieved, or almost immediately relapsed, or were lost sight of (one case). Since that time much the same degree of success has been achieved in both malignant and non-malignant cases by workers using this method or some modification of it. The literature includes papers by Yeomans (1933), Saltzstein (1934), Stern (1934 and 1936), Sloane (1935), Grant (1935), Silverstein (1935), Rowe (1935), Greenhill and Schmitz (1935 and 1936), King (1935), Babcock (1935), Abbott (1936), Meynier (1936), Russell (1937), and Todd (1937). On injection the relief of pain is often immediate, but is sometimes delayed for a considerable period—according to Dogliotti as long as forty days. In a number of cases the first injection has been unsuccessful, but pain has been completely relieved by a second. Todd (1937) in two cases found it necessary to repeat a successful injection in three months. The length of time for which the effect of treatment is felt has varied in the recorded cases. Dogliotti gave the maximum as six months, and Stern as eight months. In Todd's series the maximum period of relief was sixteen months and the average period five months.

The effects of alcohol injections upon the cord and nerve roots have been studied post mortem in a few instances: they are extremely slight. In Todd's cases they included extreme congestion of the vessels around the nerve roots and throughout the lower part of the cord, thickening and hyalinization of the vessel walls, and some perivascular deposit of hyaline fibrous tissue. Ritchie Russell reported demyelination of nerve fibres and cellular infiltration both in the posterior nerve roots and in the column of Goll in two cases examined twelve months and nineteen months respectively after alcohol injection. Dogliotti found that the cerebrospinal fluid examined a few days after an injection is under increased pressure and shows a slight increase of albumin and of leucocytes. Normal conditions are restored in about ten days.

Technique of Injection

The method used by different workers has varied somewhat, but in most cases either absolute or 95 per cent. alcohol has been given in doses of 0.2 to 1 c.cm. without previous withdrawal of cerebrospinal fluid or barbotage. In one only of the recorded cases was barbotage employed. Meynier (1936) withdraws 10 c.cm. of cerebrospinal fluid and injects an equal quantity of dilute alcohol (5 to 7.5 per cent. solution of absolute alcohol in distilled water), introducing it "rather rapidly." In view of possible dangers it is best to begin with small doses and repeat the injection, using a larger dose, if necessary. The treatment can quite well be given to the patient in bed, though it is easier to arrange and maintain the required position on an operating table furnished with a kidney bridge. A general anaesthetic is very rarely necessary, but local anaesthesia may be used if desired.

Having decided which nerve roots are to be the objective—taking into consideration the innervation of the diseased organ and the situation of the pain—the interspace to be employed for the injection is calculated from the known relation between the spinal segments and the bones of the vertebral column. The risk of injuring structures other than the posterior roots in question is minimized by introducing the alcohol as close as possible to the point of emergence of the latter from the cord. When, therefore, the lumbar or sacral roots are the objective the very general practice of making the injection through a lumbar interspace is open to criticism. Since the spinal cord does not extend, at most, lower than the first lumbar interspace, alcohol introduced below this point will come in contact with the nerves of the chorda equina, where its effects cannot be accurately localized. It is technically easier to introduce a needle through a lumbar than through a dorsal interspace, but it would seem to be much safer to use the space most nearly corresponding to the spinal segments involved.

The patient is placed on the side opposite to that on which the pain is felt: if the pain is bilateral, on the side on which it is less severe, supposing there is any inequality. The spine is well flexed in a forward direction and the head lowered either by raising the foot of the bed or by tilting the operating table. The spine is flexed laterally by means of pillows or sandbags or by elevating the kidney bridge of the operating table, so placed that the site of the proposed injection is raised and the spinal segments corresponding to the nerve roots aimed at become the highest part of the spinal cord. At the same time the body is inclined forward at an angle of 45 degrees. This brings the posterior roots into a horizontal position, where the greatest possible length is exposed to the action of the alcohol, while the motor roots are brought into a plane in which they are less likely to be damaged. The puncture is made in the midline with an ordinary fine lumbar puncture needle. When puncturing a dorsal interspace it must be borne in mind that the needle must be introduced obliquely upwards as well as forwards, in a plane almost parallel with the skin surface of the back. To avoid injury to the cord in this region it is safer to remove the stylet from the needle before it enters the theca. It is dangerous to make a puncture above the dorsal region.

As soon as the needle is well in the subarachnoid space the syringe containing the measured dose of sterile alcohol is attached and the alcohol very slowly injected, at a rate of about 0.4 c.cm. a minute. After the injection is finished the patient is kept in exactly the same position for a time sufficient to allow the alcohol to act upon the posterior roots. The period allowed for this by different workers varies from ten minutes (Stern) to two hours (Greenhill and Schmitz). At the end of that time he is placed flat on his back and left in that position for twenty-four hours. It is wise to keep the foot of the bed raised for the first few hours. If it be necessary to repeat the injection either on the same or on the opposite side an interval of five to seven days should elapse before this is done.

A feeling of burning may accompany the introduction of the alcohol, but this quickly passes off. Pain may stop immediately, or, as already mentioned, its relief may be gradual. Dogliotti observed in many of his patients that immediate cessation was followed by a temporary return of the pain, lasting for some hours or days and succeeded in its turn by gradual relief. There may also be transient numbness and weakness of the leg on the side of the injection, sometimes associated with temporary loss of the tendon reflexes. In some cases more serious

In private houses similar precautions should be taken. The infected person must never tread with bare feet where an unaffected person will step. On leaving his bath he should step on to his own bath mat, which should be removed from the bathroom as soon as he leaves. No one else should use his bath towel, and probably it is safer to swill down the bath with a weak antiseptic after he has used it. The evidence is not conclusive, but it is probable that the infection is more usually contracted in bathrooms than elsewhere. So little is known about the dissemination of the wart virus that it is better to be overcautious rather than risk dissemination of the virus by lack of caution.

In the earliest stages the warts can in most cases be destroyed by the use of a wart paint—for example:

R. Zinci chloridi 3 ss
Collodium acid. salicyl. (1 in 10) ad 3 i
Misce.

A spicule of wood should be dipped into this paint and then bored gently into the wart. The treatment should be carried out twice daily, and if the patient is placid the results are usually satisfactory. Many persons complain bitterly that they cannot stand the pain, and other measures have to be employed.

Most dermatologists prefer to use radium or x rays, and these physico-therapeutic agents are the least painful methods of treatment and the most certain in their results. In my experience, using x rays filtered through 0.5 mm. aluminium, a plantar wart requires an average of 900 r units of x rays before it succumbs. While receiving treatment it is advisable for the patient to wear white cotton socks underneath his usual socks throughout the day. These socks should be boiled every night. The feet may be powdered with an antiseptic dusting powder.

If physico-therapeutic measures are not available excision may be attempted. In my hands local anaesthesia has not been very successful: I have found it to be almost impossible to infiltrate the part with novocain without causing much pain. I prefer to use a general anaesthetic (nitrous oxide or gas-and-oxygen). The warts should be scraped out with a sharp curette. It is surprising how deeply the roots are situated. I have found it best to remove the horny collar which surrounds each wart, as recurrence is frequent if this is left. Bleeding should be controlled and the area disinfected, so far as is possible, by the application of the silver nitrate pencil. Dry dressings are usually adequate, and healing is complete in about fourteen days. Diathermy or refrigeration with carbon dioxide snow are alternative measures. Goldsmith (1936) recommends that the "snow" should be applied for three to five minutes: a large bleb will develop, allowing the wart to be painlessly excised about three days later. Good results have been claimed for treatment by cataphoresis with zinc sulphate.

Chiropodists often treat these cases successfully. They generally aim at destruction of the wart by escharotics or keratolytics. Runting (1935) states that their object is "to destroy the growth so thoroughly that such a reaction may be created in the healthy tissue as to bring about a line of cleavage between the destroyed growth and the normal healthy tissue. The culmination of this process is usually accompanied by effusion of serum or sero-pus. . . . The whole art of the successful destruction of verrucae depends upon inducing this condition effectually without causing more disturbance to the normal tissue than is actually essential to the cure." "The majority of chiropodists bring about the desired result with acids, such as nitric, acetic, monochloroacetic,

trichloroacetic, salicylic, chromic, pyrogallic, or acid nitrate of mercury; or with such powerful alkalis as potassium hydroxide or sodium hydroxide."

In the majority of cases the surrounding tissue is protected by an application of vaseline, and the acid or alkali is applied with an orange stick and "worked into the growth." A protective dressing is employed and a few days later the treatment is repeated, the tissue which has been destroyed by the previous treatment being removed before fresh acid or alkali is applied. By proceeding slowly and giving regular treatments the warts are destroyed with a minimum of pain. The use of pyrogallic acid is effective and is not associated with much pain unless the application is left *in situ* too long. The acid is applied as an ointment (30 to 50 per cent. in ung. resinae) once or twice weekly, the usual occlusive precautions being observed.

Summary

Attention is drawn to an epidemic of plantar warts among school children.

A short description of the signs, symptoms, aetiology, pathology, and treatment of the warts is given.

[The photograph in the Special Plate is reproduced from *Diseases of the Skin* (fourth edition), published by Messrs. Baillière, Tindall and Cox.]

INTRATHECAL ALCOHOL INJECTION FOR RELIEF OF PAIN: A REVIEW

BY

CONSTANCE OTTLEY, F.R.C.S.

Surgeon, New Sussex Hospital for Women; Surgeon,
Marie Curie Hospital

Dogliotti in 1931 first suggested the use of subarachnoid injections of absolute alcohol as a simple and comparatively safe means of alleviating severe chronic pain of which the cause is not amenable to treatment. He pointed out that the various surgical measures designed to relieve pain (posterior rhizotomy, chordotomy, sympathectomy) are operations to which many patients suffering from such conditions as advanced malignant disease cannot justifiably be submitted; nor are they always successful. Paravertebral nerve-blocking is an alternative, but it is difficult to carry out and is uncertain in its effects.

Dogliotti's aim in devising this method was to bring about a partial destruction of the appropriate posterior nerve roots close to their entry into the spinal cord. Accepting the assumption that pain is proportional in severity to the numerical strength of the sensory impulses reaching the centres concerned, he argued that this "decimation" of the afferent nerve fibres should reduce the pain-provoking stimulus below threshold value. From animal experiments he satisfied himself that it is possible to limit the action of the alcohol with sufficient precision to the posterior roots; only when the doses used were excessive did symptoms of motor paralysis follow the injections.

Principles of Treatment

The principle underlying the method is that absolute alcohol possesses a specific gravity considerably lower

advice to a new parent attending the clinic is in regard to a balanced dietary, but with the children under consideration this was avoided in order to demonstrate the effect of the addition of iron to their normal meals. After a course of iron appetites improved, the mucous surfaces became less pale, and the children became more active and showed an increased vitality generally.

It will be noted from the tabulated results given below that there was a definite rise in the percentage of haemoglobin. From the clinical improvement noted in the children this was expected. In order to avoid giving a detailed account of the rise in the percentage of haemoglobin and the blood pictures obtained from each child, a table is appended to show the average rise in haemoglobin over the series of children who attended weekly for examination. The blood picture is the average for thirty-one children, but since the attendance for examination diminished each week, owing to ailments and lack of co-operation from parents, the results given at the end of the sixth week are completed from a smaller number. Clinically, however, all the children maintained their immense improvement in health and general activity while taking a daily dose of iron. Considering that the iron cost the parent only 1½d. per week one feels it to be worthy of trial in any case where a child shows a lack of normal vitality. Had advice regarding diet been given in conjunction with the addition of iron to the food we could have obtained a more pronounced rise in the haemoglobin percentage and a greater improvement in the general health of the children. It is gratifying to note that some firms who market dried full-cream milk are now adding an adequate dose of iron to the food, and not the small amount so often met with a few years ago, an amount which would fail to give any satisfactory rise in haemoglobin.

Table showing the Blood Picture before giving Iron to Thirty-one Children (Average Age, 2½ Years)

Average number of red blood cells per c.mm.	3,340,000
Average percentage of haemoglobin ..	66
Percentage showing anisocytosis ..	84
" " pallor ..	35
" " poikilocytosis ..	16
" " polychromatophilia ..	7
" " punctate basophilia ..	3

Conclusion

Many of the children attending a toddlers' or infant clinic under the direction of a local authority show a clinical anaemia (confirmed by blood pictures) although no definite defect appears to be present, apart from sub-nutrition and pale mucous surfaces. These children should be given a regular daily dose of iron over a period of at least six to eight weeks, even though they are getting insufficient food. If their blood picture does not show an improvement further investigation will be necessary. Where the clinical finding fails to suggest a physical defect the administration of a course of iron on empirical grounds will often save much further investigation of a more difficult nature.

Table showing the Average Percentage of Haemoglobin at the End of Each Successive Week while taking a Daily Dose of 20 grains of Ferri et Ammon. Cit.

Before taking Iron	Weeks After taking Iron					
	1	2	3	4	5	6
66.6	66.6	69.5	73.7	74.7	75.9	73.0

Summary

1. The average blood picture of thirty-one children under the age of 5 years (average age 2½ years) is given, showing signs of anaemia clinically.

2. A table is included to demonstrate the effect of a simple addition of iron to children's diet, which is left unchanged in other respects.

3. These children were chosen from a welfare centre in a poor-class district in Birkenhead, where unemployment is prevalent.

4. The cost to the parent per child per week amounted to 1½d. for the ferri et ammon. cit.

5. No advice was given to parents regarding diet for children.

We wish to thank Dr. D. Morley Mathieson, Medical Officer of Health, Birkenhead, for granting us the facilities for carrying out this work.

Clinical Memoranda

Block Anaesthesia for Insertion of Radium to Epithelioma of Lip

(WITH SPECIAL PLATE)

The use of block or local anaesthesia, either alone or combined with gas and oxygen or any other general anaesthetic, often seems to be neglected, perhaps through lack of opportunity or from prejudice on the part of the patient, the anaesthetist, or the surgeon. The following account appears to be worthy of record as illustrating the indispensable use of block anaesthesia in a case which presented considerable difficulty with regard to the anaesthetic.

The patient, a man of 77, was suffering from an extensive epithelioma of the lower lip. The growth involved the left corner of the mouth and extended along the lower lip to within half an inch of the right corner. The patient was frail and quite unsuitable for a general anaesthetic, and had given cause for great anxiety when under gas and oxygen for the extraction of teeth. The intravenous barbiturates were out of the question in view of the patient's age and general condition, so local anaesthesia seemed to be the method indicated. Local infiltration is not ideal for radium cases, as the ensuing soginess of the tissues, added to the reaction of the radium itself, is apt to cause more sloughing than is usual. The only solution appeared to be in block anaesthesia sufficiently far away to leave the operation site untouched.

An hour before operation the patient was given one-sixth grain of morphine and 1/150 grain of hyoscine, and fifteen minutes before operation a right and left mandibular injection by the indirect method, 2 c.cm. of anaesthetic fluid being injected at each inferior dental foramen. To anaesthetize the left corner of the mouth the infra-orbital nerve was dealt with by the deposition of 2 c.cm. of anaesthetic fluid at the left infra-orbital foramen and gently massaged upwards. On being questioned the patient now said that his lower lip was tingling and he was unable to feel the prick of a needle, proving that the mandibular injections were working efficiently. Each of the long buccal nerves was injected with 1/2 c.cm. to anaesthetize the mucous lining of the lip. All these injections were of course given inside the mouth. The patient's eyes were then bandaged and he was taken into the theatre, the towels placed in position, and the lip prepared. After the insertion of the first radium needle the patient fell asleep, and remained asleep and snoring until roused by the removal

motor disturbance has occurred, such as paraplegia, retention of urine, or loss of control of the sphincters. For the most part these symptoms have passed off after some hours or days; in a few of the cases a greater or less degree of disability has persisted. Silverstein's patient, a tabetic, was left with complete motor and sensory paralysis of the leg, but in this case an unusually large dose of alcohol (9 c.cm.) was given. In Sloane's patient, also a tabetic, there was retention of urine and faeces, abolition of the ankle-jerk and paresis of the muscles of the lower leg on both sides—more pronounced on the side of the injection—and anaesthesia of the back of the thigh and leg and of the peri-anal region, complete on the side of the injection and partial on the opposite side; a certain degree of weakness of the legs and difficulty with micturition was permanent. Babcock also observed persistent weakness of the leg. In one of Todd's cases a meningeal reaction occurred, but this subsided spontaneously in four days. One death has so far been reported—by Abbott, in a patient in the last stages of malignant disease who died the day following the injection. Russell's series of twenty-five cases included one case of retention of urine and three cases of sphincter paralysis; and among Todd's eighteen cases retention of urine and incontinence of faeces occurred in two and incontinence of faeces alone in one. In all these cases, and in others reported in the literature, recovery took place within a few days. The longest time taken for recovery from these sphincter disturbances has so far been two weeks. One case of diarrhoea lasting three weeks has been reported (Greenhill and Schmitz).

The comparative rarity of motor disturbances after subarachnoid injection is probably due in part to the relative insensitivity to alcohol of motor as compared with sensory fibres; it is difficult otherwise to understand why these disturbances do not more often accompany injections given in the region of the cauda equina.

One case may be added to those collected from the literature. This patient, a woman of 57, was suffering from intense pain in the right side of the abdomen associated with generalized melanotic disease of the liver, secondary to a malignant melanoma of the choroid for which the right eye had been removed five years before; the pain was constant and relieved by morphine only to a very slight extent and for an hour or two at a time; she was worn out from lack of sleep. The diagnosis having been confirmed by exploratory laparotomy and biopsy, 10 minims of 95 per cent. alcohol were injected through the seventh dorsal interspace. The injection was wholly unsuccessful. It was therefore repeated a week later, the dose being increased to 20 minims. This time relief was immediate and complete. Neither injection was followed by complications of any kind.

THE EFFECT OF IRON ADMINISTRATION IN CASES OF SUBNUTRITION

BY

E. BLACKSTOCK, M.D., B.Ch., B.Sc., D.P.H.

Assistant Medical Officer, Birkenhead

AND

J. M. RITCHIE, M.A., M.D., Ch.B., D.P.H.

Pathologist, Birkenhead

It is a pity that medical officers in charge of a welfare centre under the control of a local authority do not more often publish their experience at the centres. The number of children attending is usually large and the work done excellent, but the amount of literature relating to these clinics is much too small. One realizes that the difficulties of research work are many, the greatest of them being the lack of co-operation from parents. Numerous plans are conceived and much work started; but the result is *nil*, as parents will not bring their children along for examination often enough, and so results that are promising cannot be put in the tabulated form necessary for publication. This is a great loss to the general practitioner, who often has little chance of obtaining experience in the pathology or even the physiology of infant life during his first few years of practice. The following work was carried out partly at a toddlers' clinic (children from 1 to 5 years old) and partly at the laboratory, both under the control of a local authority (county borough, population 150,000). For reasons already mentioned the figures were not nearly so complete as one would desire, but they are of value as showing a positive result from a simple and cheap form of therapy for a certain defect prevalent among children in the poorer-class districts of many boroughs.

At the clinic under consideration the children attending belonged to families whose chief breadwinner was often unemployed for long periods, and whose food was therefore mostly of the cheap variety. The proteins necessary for adequate growth were seldom present in the daily menu. The children's food consisted in the usual energy-producing carbohydrates, mostly in the form of wheat of different millings made edible by the addition of animal or vegetable fat. During the summer first-class proteins such as eggs, fish, and meat could be bought, but in the winter, when these foods were most necessary, they were often lacking, and malnutrition therefore followed.

Many of the children attending the centre had pale mucosae, and showed lack of energy, anorexia, subnutrition, and dullness of spirit. It was decided to try the effect of the addition of iron to their diet, unaided by anything else that might cause a diminution in the existing subnutrition. The children were chosen and sent to the laboratory, where complete blood examinations (cell count, films, and haemoglobin estimation) were carried out. In order to reduce the passive opposition of the parent the blood examination was made only at the first attendance, subsequent investigation being confined to estimation of the percentage of haemoglobin. In this way we could eliminate those children who were not actually anaemic though appearing so on clinical examination. All the children selected, however, were anaemic both on clinical and on biological grounds.

The parents were not advised regarding diet, but were merely given a bottle of ferri et ammon. cit. to be taken by the children once daily in any form of food. The first

Reviews

ELECTROCARDIOGRAPHY

Clinical Electrocardiography. By Sir Thomas Lewis, M.D., F.R.S., D.Sc., LL.D., F.R.C.P. Sixth edition. (Pp. 128; 109 figures.) London: Shaw and Sons, Ltd. 1937.

The Fundamentals of Electrocardiographic Interpretation. By J. Bailey Carter, M.D. (Pp. 326; 250 figures. 20s.) London: Baillière, Tindall and Cox. 1937.

It seems that few cardiologists escape the urge to write a textbook on electrocardiography. In fact there are too many such books, and too few readable and concise accounts of the clinical aspects of cardiovascular disease. It is true that no investigation of heart disease, known or suspected, is complete without electrocardiography, but there is a tendency for instrumental methods to be given too dominant a place among the means at the disposal of the clinician. One of the earliest and best brief accounts of electrocardiography was given by Sir Thomas Lewis, and the sixth edition of his *Clinical Electrocardiography* presents a useful outline of the method and of the interpretation of the curves obtained in the common disorders of the heart. In his section on coronary thrombosis the author emphasizes the importance of correlating the electrocardiogram with the other clinical evidence before arriving at a diagnosis.

Dr. J. Bailey Carter, in *The Fundamentals of Electrocardiographic Interpretation*, has produced a comprehensive survey of the subject. The earlier sections of the book give an account of the principles and technique of the method, and these are succeeded by orthodox accounts of the common abnormalities of rhythm. A discussion of the electrocardiographic aspects of myocardial disease makes reference to chest leads. The author has given a description of the curves likely to be obtained in certain forms of heart disease, such as congenital lesions and mitral disease, and in addition has mentioned the anomalies often seen in certain general disturbances of bodily function, such as myxoedema and diabetes, and in toxic conditions such as pneumonia and diphtheria. The 250 figures (mostly electrocardiograms) suitably illustrate the text, though the records themselves or the reproductions of them are not all of equally high standard. This is a valuable book in which a serious attempt has been made to present an up-to-date outline of electrocardiography in its true perspective and without elaboration of debatable matters.

ARCHIVES OF NEUROLOGY AND PSYCHIATRY

Archives of Neurology and Psychiatry from the Central Pathological Laboratory of the London County Hospitals for Nervous and Mental Disorders. Edited by Frederick L. Golla, M.B.Oxon., F.R.C.P. Volume XIII. 1937. London County Council. P. S. King and Son, Ltd.

It has sometimes been said that the administration of hospitals or laboratories by local authorities was likely to kill originality and discourage enterprise. The present volume is the best possible refutation of such a doctrine. In this Professor Golla has collected forty-eight papers dealing with various aspects of neurology and psychiatry which have emanated from the special institutions under the control of the London County Council. All these papers have been issued before in various publications and appear here without resetting and therefore in a variety of types and styles. It seems a pity that the typography could not have been made uniform.

However, if the manner leaves something to be desired the matter is full of interest. There are studies of Berger's rhythm in cerebral tumours and in epilepsy, records of basal ganglia syndromes, and certain biochemical observations as well as studies on the effect of benzedrine, mescaline, evipan, and bromides on cerebral function. Papers on neurosyphilis are contributed as well as on encephalitis lethargica, polyneuritis, etc.

In the psychiatric section are several papers dealing with experimental psychology, while others are more purely clinical. An interesting genetic paper is contributed on dissimilarity of monozygotic twins, and there are a few papers on matters relating to mental deficiency. This is the thirteenth volume of the series, and as has been indicated above it is a tribute to the healthy activity of the scientific work carried out under the auspices of the London County Council.

NATIONAL EDUCATION

The Silent Social Revolution. An Account of the Expansion of Public Education in England and Wales, 1895-1935. By G. A. N. Lowndes. (Pp. 274; 14 illustrations. 2s. net.) London: Humphrey Milford. Oxford University Press. 1937.

Not so very long ago the National Union of Teachers issued a remarkable publication entitled *The Schools at Work*. With very little letterpress but with abundant pictorial illustration it set out in a very vivid and at times pathetic way what our schools are now doing and the contrast between all this and the state of things forty to fifty years ago. We now have in *The Silent Social Revolution*, by Mr. G. A. N. Lowndes, an equally remarkable volume, to which the earlier publication may be regarded as an introduction, but to which it might well have been an addendum, giving a relatively full and detailed account of "The Expansion of Public Education in England and Wales, 1895-1935." The author states that existing literature bearing upon this subject seems to him "to be duller than the intrinsic interest of the subject warrants," and most readers will agree with him. They will the more gladly welcome this comprehensive, accurate, orderly, well-written, and restrained humorous "account." It is an account in two senses: historical and, being so well done, therefore strongly illuminative; and economic, balancing the gains and the cost of a vast social change. In the former aspect worthy tribute is paid to those whose names should never be forgotten in this connexion, particularly Sir John Gorst, Sir Michael Sadler, Mr. A. J. Balfour (as he then was), and Sir Robert Morant. In the latter aspect it is said: "Whatever may be the ultimate verdict of the social historian of the future upon the efforts made by successive British Governments, in co-operation with the local authorities, to repair in three decades the neglect of three centuries, this much is certain, that their efforts have quite outstripped the capacity of the man in the street to keep abreast of what has been happening"; and again, "Although most people will readily assent to the dictum that educational expenditure is long-range expenditure, few are qualified to prove its truth by showing what the long-range expenditure incurred by past generations has achieved."

A widespread ignorance or indifference as to education still prevails in several sections of the population, and each year there are still voluminous and verbose aspersions on the value and methods of our modern schools. Constructive criticism and suggestions are always valuable, but judgments made without any real knowledge or understanding of what is actually being done are of no use. The present volume sets out more completely and

of the bandage from his eyes at the completion of the operation.

A dental syringe fitted with a fine 42-mm. needle was employed. The anaesthetic used was procaine solution with epinephrin (novol)—each cubic-centimetre containing 0.02 gramme of procaine hydrochloride (novol) and 0.00003 gramme of epinephrin made isotonic with buffer salts.

I am indebted to Miss Lewis, M.S., F.R.C.S., for permission to publish this case and also for the loan of the photograph of the patient.

Honorary Consulting Anaesthetist, Eastman
Dental Clinic.

Foreign Bodies in the Intestinal Tract

The surgeon is often obliged to perform operations for removal of foreign bodies from the intestinal tract. The patients are mostly children in whom the swallowing of a foreign body has been accidental or mental patients with whom it is either a symptom of disease or an attempt at suicide. In these cases the operation is nearly always performed from fear of subsequent "perforation" or to remedy intestinal obstruction. Furthermore, the identity of the foreign body is usually known.

The following case is of special interest because of the difficulty in diagnosis which was presented both to clinicians and to radiologists.

CASE RECORD

A male convict in the Shanghai municipal gaol, aged 24, was admitted to hospital complaining of pain and swelling on the right side of the abdomen. He could recall no other serious illness, and the family history was very vague and essentially negative. The onset of the illness was apparently insidious, but the patient referred to attacks of pain in childhood, and vaguely mentioned having swallowed some fruit-stones many years ago. For the past ten years he had suffered from frequent attacks of acute colicky abdominal pain, lasting some two hours on each occasion. These attacks were not associated with vomiting or diarrhoea and had no relation to food. He also stated that for over ten years he had had a swelling in his right side. Bowel action was regular and without pain. The present attack was identical with previous ones.

Examination.—The patient was well developed, without any signs of wasting. The cardiovascular, pulmonary, and nervous systems and the urine showed no abnormalities. The stools contained no ova. Examination of the abdomen revealed no tenderness or rigidity. The liver, spleen, and kidneys were not palpable. A round firm non-tender mass was palpable to the right of the umbilicus: it was mobile and also moved with respiration. There was no definite edge to the tumour. The differential diagnosis based on the presence of this tumour associated with a history of attacks of colicky pain was as follows: hyperplastic tuberculosis of caecum; carcinoma of colon; gall-stones; appendicular abscess; renal calculi; tuberculous glands; and actinomycosis. To these were added, after the first examination, "gall-stones passed through common bile duct but retained in ileum" and "calcified hydatid cyst."

X-Ray Examination.—Having committed ourselves to the above differential diagnosis the patient was submitted to the following x-ray examinations: (1) barium meal and enema, (2) cholecystography, (3) pyelography, performed in that order. The first report, on items (1) and (2), was: "Sixteen large 'ring' shadows in right iliac region; they are not in a dilated gall-bladder, as a normal dye-filled gall-bladder is shown. They appear to be a dilated terminal ileum, and are probably 'foreign bodies' which have been swallowed." The second report stated: "Kidneys normal and not related anatomically with the shadows."

Operation.—The diagnosis of the first report was tentatively agreed upon, and, since the patient still continued to have attacks of pain and asked for operative intervention, a laparotomy was performed by right paramedian incision. A loop of the ileum was found adherent and twisted upon itself. There were no signs of inflammation. Hard masses like "pebbles" were felt inside the loop of gut "as if in a bag" and made loud "clicking" sounds when handled. Fifteen of these were delivered through a small opening made in the wall of the ileum (the sixteenth could not be found), the opening in the ileum was sutured and the abdomen closed. Although the sixteenth "foreign body" was subsequently seen by x rays, the patient made an uneventful recovery and was returned to gaol free from these attacks of pain.

THE "FOREIGN BODIES"

The fifteen "foreign bodies" removed were all more or less spherical in shape, save one which was flat. They were heavy (average weight 2.66 grammes), resembled

pebbles of a greenish-brown colour, and were very smooth. The size is shown in the illustration. They were easily crushed, and were found to be laminated. The nucleus in each stone crushed was a fruit-stone with an average weight of 0.352 gramme.

Extract from the Analyst's Report.—"Analysis showed the powdered concretion to contain 3.9 per cent. moisture and 60 per cent. calcium oxalate, together with traces of calcium and magnesium phosphates. No carbonates and no ammonia were detected. Continuous extraction with ether in a Soxhlet apparatus yielded a substance consisting chiefly of fat, and amounted to 1.2 per cent. of the dried concretion. Qualitative tests on this extract showed the presence of cholesterol in very small amount."

CONCLUSION

It was concluded that the vague story of swallowing fruit-stones during childhood was correct, and that these fruit-stones, instead of passing normally through the intestinal tract, had been retained in a loop of the terminal ileum, where they formed the nucleus of the "stones" removed, having during the passage of years become encrusted with deposits of the oxalate and phosphate salts of calcium and magnesium and traces of cholesterol.

Our thanks are due to the Commissioner of Public Health and the Commissioner of Police for permission to publish this case; to Mr. L. H. Barton, who made the analysis of the "stones"; and to our Chinese medical colleagues for the able assistance which they gave in the treatment of the case.

Shanghai.

A verbatim report of the proceedings of the twenty-third annual conference of the National Association for the Prevention of Tuberculosis, held at Bristol in July last, is now published. The subjects discussed at the conference were: (1) propaganda and publicity methods; (2) preventive institutions (with special reference to open-air schools); (3) equipment and activities of a tuberculosis dispensary. Addresses were also given on the inquiry into tuberculosis in the island of Cyprus. Copies of the transactions may be obtained from the Secretary-General, N.A.P.T., Tavistock House North, Tavistock Square, W.C.1; price 7s. 6d. each, post free.

peutic considerations of diseases of the eye; and diseases of the outer coats of the eye. In the first of these the reader is conducted as it were through a complete examination of the eye by the simplest and oldest methods to the elaboration of these which new instruments and new methods of illumination and magnification have given to us. The balance of emphasis is admirably maintained, and the clearness of exposition is perfect. The second section is one that is a first-class test of the judgment of the author. Congenital and developmental anomalies are almost as many as the sands of the sea. Every one of them has some point of interest. A mere collection of such anomalies may exhibit the chaotic fascination of the junk shop of the antique dealer. But the wise collector will so marshal his exhibits as to display the trend of development in such a fashion as to be instructive in the highest degree. This the author has done. In the more clinical sections the handling of the diseases of the cornea is of great merit in its completeness and its suggestiveness. To each of these sections and to their subdivisions there is a well-selected bibliography.

The author has continued that very human feature of his first volume, the reproduction of the portraits of some of the masters of ophthalmology for whose work both ophthalmologists and their patients are daily debtors, and it is interesting to find that the portrait of Treacher Collins faces the introduction to congenital anomalies. We are sure that this second volume will receive as warm and appreciative a welcome as the first, and that in this welcome the author will find an encouragement to proceed with all speed to the issue of the third and final volume. It is scarcely necessary to add that the work of the printer, both in the text and in the illustrations, is of the highest order.

Notes on Books

Dr. BRONSON CROTHERS is well known as a paediatrician with a special interest in neurology, which naturally brings him up against the difficult question of behaviour problems of children in and out of hospital. *A Paediatrician in Search of Mental Hygiene* (Humphrey Milford, 8s. 6d.) is chiefly concerned with the difficulties of liaison between child guidance units and children's hospitals in America, where it sometimes appears from the literature that there is a good deal of rigidity and want of tolerance of each other on the part of the various specialists concerned, though this is probably more obvious in theory than in practice. That difficulties exist there can be no doubt, and they are as real in this country as anywhere else, and therefore all those concerned will gain much from a study of this book, in which the differences in outlook of the paediatrician and the psychiatrist are freely discussed. Further problems, such as the small number of psychiatrists interested in children and the difficulty of fitting the psychologist and psychiatric social worker of the child guidance team into a hospital unit, are dealt with. Finally Dr. Crothers describes a co-operative unit modified from the child guidance plan which has been set up in the Boston Children's Hospital to deal with problems of behaviour and adjustment in the hospital's clientele.

We have received a copy of the *Periodica Medica* (Leipzig, Georg Thieme, RM. 3), which, as its subtitle states, contains a list and abbreviations of the most important journals of medicine and the allied sciences. The work, which is now in its third edition, has been compiled by Generaloberarzt Dr. Max Kuntze of Berlin and edited by Professor Kurt Klare Scheidegg, and contains 3,449 entries.

Preparations and Appliances

AN AID IN THE TREATMENT OF VARICOSE ULCER

Dr. JOHN FRANKLIN (London, W.1) writes:

Edward Taylor Ltd. prepared for me at my suggestion last year circular pads of sponge rubber half an inch thick and three inches in diameter coated with the same plaster mass that is used on "flexoplast" elastic adhesive bandages. I have found that the healing time of varicose ulcers has been shortened very considerably by the application of one of these pads to the surface of the ulcer before putting on the elastic adhesive bandage. Where the area of ulceration is more extensive than three inches in diameter, pads of the requisite size and shape may be cut out of large sheets of the material. The pad and elastic bandage is changed every one, two, or three weeks, following the usual technique employed in treating varicose ulcer with elastic adhesive bandages.

TWO OINTMENTS

"Desitin" ointment (Desitin Products Ltd., Park Royal Road, N.W.10) is compounded with vaseline, lanolin, and cod-liver oil, and also contains zinc oxide and talc. The vendors quote numerous favourable references from medical literature regarding the wound-healing action of the ointment.

"Esiderm," made by the same firm, is a non-greasy ointment which is compounded with glycerin and water, and contains zinc oxide, talc, and Kieselguhr.

LIVER EXTRACT FOR PARENTERAL USE

"Reticulogen" (Eli Lilly and Co.) is a liver extract for parenteral injection, combined with vitamin B₁₂. Each ampoule (0.5 c.c.m.) contains the haematopoietic equivalent of nearly 10 lb. of fresh liver and, in addition, 500 international units of vitamin B₁₂. The manufacturers supply an interesting pamphlet in which they recount the remarkable therapeutic success of parenteral liver therapy, and mention that during the past decade the mortality due to pernicious anaemia has fallen by 60 per cent. The disorders of the central and peripheral nervous system in pernicious anaemia have proved more refractory to treatment than have the blood changes. Various authorities have advocated the use of vitamin B₁₂ for the relief of the nervous disorders, and for this reason that vitamin has been included in the preparation.

A NEW LOCAL ANAESTHETIC

"Metycaine" (Eli Lilly and Co.) is a new local anaesthetic, the chemical name of which is gamma-2-methyl-piperidino-propyl benzoate hydrochloride. The toxicity of this compound by subcutaneous injection is similar to that of procaine, and therefore much less than that of cocaine; when administered intravenously, however, it is more toxic than procaine. Metycaine is superior to procaine, as it can penetrate mucous membranes, and hence is useful for ophthalmic, oral, nasal, and urogenital application. It can be used for hypodermic administration in the same manner as procaine. The makers recommend it for spinal anaesthesia, and state that its action is more enduring than that of procaine. It is supplied for spinal anaesthesia in a 10 per cent. solution, and the dose required lies between 40 mg. and 200 mg. of the drug, or 0.4 c.c.m. and 2 c.c.m. of the solution.

SULPHONAMIDE EMULSION

Emulsion of sulphonamide (Wyleys Ltd., Coventry) is a palatable preparation containing 7½ grains (0.5 grammes) of pure p-aminobenzenesulphonamide in each fluid drachm (4 c.c.m.). The drug is present as a fine powder suspended in water, and the mixture contains nothing in addition except a simple emulsifying agent. The oral administration of sulphonamide has become established as an effective method of treatment of disease due to infection with haemolytic streptococci (acute puerperal sepsis, erysipelas, tonsillitis, etc.), and its action in numerous other forms of infection is being investigated intensively. Emulsion of sulphonamide provides a convenient and agreeable method for the administration of this important drug.

accurately than any other known to the reviewer—the case for public education: it supplies abundant material—historical, social, and statistical—for those who wish to make an intelligent assessment in this sphere, or who would like to be helped and encouraged in their presentation of the case to any public which remains sceptical. As has often been said in this *Journal*, education and health are not subjects which are really separable, but many of our readers will be particularly interested in what is said of the school medical service. They will find that the author says with regard to this: "One wonders if any nation has ever spent £2,000,000 a year to better advantage," and that full justice is done to the work of Sir George Newman. There may, however, be a little regret that the author has failed to note the decisive influence of the British Medical Association upon both the initiation and progress of this service. It may be worth pointing out that in the particular copy of the book sent for review pages 177 to 192 are reduplicated. This oversight—or lack of oversight—is embarrassing; but it may not have occurred in other copies.

EXPERIMENTAL PHARMACOLOGY

Handbuch der Experimentellen Pharmakologie. By A. Heffter. Vol. V. Edited by W. Heubner and J. Schüller. (Pp. 307; 24 figures. RM. 39.60.) Berlin: Julius Springer. 1937.

The fifth supplementary volume of Heffter's textbook of experimental pharmacology contains the following articles: chaulmoogra oil, by Professor Schlossberger of Berlin; coramine and cardiazol, by Professor Hildebrandt of Giessen; the harmine alkaloids, by Professor J. A. Gunn of Oxford; insulin, by Professor Geiling of Chicago and Drs. Jensen and Farrar. The articles on coramine and cardiazol are of particular interest, since these drugs have attained great clinical popularity. The experimental work reviewed shows that there is little evidence for any direct cardiac action. The author gives a full review of the extensive literature regarding the stimulant action of these drugs on the central nervous system.

The article on insulin by Geiling and his co-workers gives a very clear summary of the experimental evidence, and the authors deal fully with various difficult problems, such as the factors regulating insulin secretion, the manner in which insulin acts on the blood sugar, and the influence of the pituitary gland on the secretion and action of insulin. The speed and success with which the therapeutic use of insulin has been developed form a striking contrast to the difficulties which have attended the analysis of its physiological action. Professor Schlossberger's article on chaulmoogra oil and related compounds gives a summary of the recent chemical and pharmacological literature relating to fatty acids which contain cyclic groups. The very large literature quoted shows that a surprisingly large amount of work has been done on this subject during the last decade. Professor Gunn, in his article on the harmine group, gives a brief account of the very varied pharmacological actions of members of this group.

TUBERCULOSIS OF THE ALIMENTARY TRACT

Tuberculose du Tube Digestif. By André Cadé, Paul Santy, and Jean Heitz. (Pp. 410; 27 figures. 85 fr.) Paris: Gaston Doin et Cie. 1937.

This work serves as a reminder of the possible existence of tuberculous lesions in every part of the alimentary tract (infinitely rarer in some situations than in others), and of the fact that tuberculosis may involve organs, such

as the appendix, without producing the typical histological changes. It attracts attention, too, to the frequency with which simple inflammatory and nervous derangements of the digestive system are associated with tuberculous disease elsewhere; thus dyspepsia is one of the commonest symptoms of phthisis. The body of the book is divided into four parts. In the first are discussed the various aspects of tuberculosis of the buccal cavity, including the tongue, the gums, the mucosa of the cheeks, the palate, and the lips; and the second surveys tuberculosis of the oesophagus. The part describing tuberculosis of the stomach contains also discussions on the relation of simple ulcer to tuberculosis and on the dyspepsias and forms of gastritis associated with tuberculosis of other organs. The fourth section, on tuberculosis of the intestines, deals separately with the generalized form and the forms localized to the small intestine, the ileo-caecal region, the appendix, the colon, the rectum, and the anal and perianal regions.

The book is written in textbook style, more adapted to the student than to the practising physician or surgeon, who will find the volume of little assistance in clinical work. The contents are not quite up to date, as is exemplified by the treatment of tuberculous enteritis; and the illustrations are inadequate in relation to the subject-matter, though a word of praise must be given to the four excellently reproduced x-ray photographs of tuberculous enterocolitis. The work will, however, be found very useful for purposes of consultation, particularly as there is an appendix which contains over a thousand references classified according to subject.

DUKE-ELDER'S OPHTHALMOLOGY

Text-Book of Ophthalmology. Volume II. Clinical Methods of Examination, Congenital and Developmental Anomalies, General Pathological and Therapeutic Considerations, Diseases of the Outer Eye. By Sir W. Stewart Duke-Elder, D.Sc., Ph.D., M.D., F.R.C.S. (Pp. 2094; 742 illustrations, including 24 coloured plates. 63s. net.) London: Henry Kimpton. 1938.

The second volume of Sir Stewart Duke-Elder's *Text-Book of Ophthalmology* will be received with interest and critical appreciation by all English-speaking ophthalmologists. In reviewing the first volume, which was published in 1935, we wrote:

"This first volume is in our judgment a great book. It is great by reason of its bulk, for it exceeds a thousand pages; it is great in its conception, and also great in its achievement. The author may well be congratulated upon such a piece of work—upon his ability to produce it and his industry in producing it. The standard he has set himself in this first volume, which deals with matters which have been particularly the subjects of his study, will make this succeeding task—that of embracing the many-sided aspects of clinical ophthalmology—difficult indeed, and the more meritorious will be his achievement if he wins through. In that event we may say with assurance that there will be no work on ophthalmology in the English language to match it."

—This second volume is fully up to the high standard set by the first, and wholly justifies the interest and expectation aroused in the author's work. It accounts for another thousand pages, yet there is no inflation of material, but rather there is shown a real economy of words. The size is dictated by the subject-matter, for the book aims to be encyclopaedic. For an individual worker, in the full practice of his profession, to have produced two such volumes is a great achievement.

The second volume comprises four sections: the clinical methods of examination of the eye; congenital and developmental anomalies; general pathological and thera-

additional twenty beds. As a memorial to Prince Albert the Royal Albert wing was added in 1862, the cost being £2,900; and six years later a children's ward of twelve beds was provided.

Less than forty years after the hospital had been opened the governors came to the conclusion that in consequence of serious structural defects a new one was desirable. Accordingly they bought the site of the present imposing buildings for £5,000, and in 1881 erection was begun. Altogether the hospital cost over £38,000, practically the whole of this sum being raised locally. Many substantial

into a Medical Board to consider questions submitted to them by the committee of management. Other developments included in 1912 an enlarged theatre block dedicated by the Bishop of Exeter in memory of Dr. Connell Whipple. The cost was met by friends, who contributed £400. Four years later a mortuary chapel was completed, and in 1918 buildings were erected for the treatment of venereal diseases, the cost being defrayed by the Devon County Council, Cornwall County Council, and Plymouth City Council. In the following year the Mildmay hut was presented for pensioners requiring orthopaedic treatment,

Men's Ward, Orthopaedic Hospital, Mount Gold, Plymouth.
(Block lent by Messrs. Ed. J. Burrow and Co., Ltd., Cheltenham and London.)

bequests were made. Mrs. Haines gave nearly £30,000 for, among other things, the erection of a wing in memory of her brother, John Hay. The gifts of Sir Massey Lopes of Maristow, near Plymouth, amounted to something like £20,000, and two medical wards endowed by him are known as Lopes and Maristow. It is interesting to note that Henry Lopes, a son of Sir Massey, is now the president of the hospital. The names of other benefactors are recalled in the various wards: Mount Edgcombe, Rooker, Gill, Prance, Radford, Bewes, Dawson. To commemorate Queen Victoria's Diamond Jubilee, friends of the hospital gave £1,148 for the maintenance of unendowed beds in the John Hay wing. As an indication of the hospital's increasing usefulness it may be pointed out that in 1900 in-patients totalled 1,483, and the daily number of occupied beds 135, with an average stay of thirty-six days at a cost of 3s. 11½d. a day, the operations numbering 620; and out-patients 2,599, with 366 operations.

In 1898 the physicians and surgeons formed themselves

The Prince of Wales's Hospital, Devonport (formerly Royal Albert).
(Photo, Abrahams, Devonport.)

and subsequently a similar hut for convalescent patients was given by the staff of the Territorial Hospital, then established at Salisbury Road schools. A sum of £2,500 was voted by the British Red Cross Society for sleeping quarters for the nursing staff, and £6,000 was received from the National Relief Fund.

To keep abreast of the times, a massage and electro-therapeutic department and a new building for pathological work were provided, deep-therapy plant installed, and an ultra-violet-ray lamp added to the electrical

department. In 1928 Princess Mary, Viscountess Lascelles, laid the foundation stone of a new block, which was not opened until January 8, 1936. This extension cost £20,000, towards which £9,000 was allocated from the proceeds of a fair and fête attended by the Duke of Windsor, then Prince of Wales and Lord High Steward of the city. This ambitious effort, the largest of its kind organized in Plymouth, realized nearly £15,000. Provision has been made for paying patients, and a scheme whereby persons in receipt of incomes below a certain limit are

ONE HUNDRED AND SIXTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION PLYMOUTH, 1938

THE one hundred and sixth Annual Meeting of the British Medical Association will be held at Plymouth next summer under the presidency of Dr. Colin D. Lindsay, emeritus physician to the Prince of Wales's Hospital, Plymouth. The Sectional Meetings for scientific and clinical work will be held on Wednesday, Thursday, and Friday, July 20, 21, and 22, the morning sessions being given up to discussions and the reading of papers. The Annual Representative Meeting for the transaction of medico-political business will begin on the previous Friday, July 15. The full list of presidents, vice-presidents, and honorary secretaries of the seventeen Scientific Sections was printed in the *Supplement* of February 5. Other details of the arrangements for the Annual Meeting will be given in subsequent issues. We publish below the second of a series of descriptive and historical articles on Plymouth and its medical institutions. The first article appeared in the *British Medical Journal* of January 1 (p. 32).

THE HOSPITALS OF PLYMOUTH

"How many desolate creatures on the earth
Have learnt the simple dues of fellowship
And social comfort in a hospital,
As Marion did! She lay there, stunn'd, half trained,
And wished at intervals of growing sense,
She might be sicker yet, if sickness made
The world so marvellous kind, the air so hushed,
And all her wake time quiet as a sleep."

The manner in which the medical profession in Plymouth have paid "the simple dues of fellowship," as Elizabeth Barrett Browning so beautifully put it, to their suffering fellow men and women illuminates some of the nobler pages of the city's long and outstanding history. The task has not been easy, for although, generation after generation, leading physicians and surgeons have willingly given of their time and skill in the art of healing, the institutions where they have laboured, relying for their existence upon voluntary financial support, have too often been faced with the handicap of debt. This remains true, even more so, to-day. But that has never daunted those upon

as the Prince of Wales's Hospital. Under this merger the available number of beds is 374. In the year ended December 31, 1936, the number of people who received treatment was nearly 22,000, and over 320 beds were occupied daily. The medical, nursing, technical, and supporting staffs total 354. The daily food bill is £30, and the wages absorb £21,000 per annum. The number of motor accidents treated in 1936 was 355. These figures give some idea of the activities of the hospital. Maybe they are small compared with similar institutions in the larger centres; but Plymouth's population is not much over 200,000, so it will be realized that the service is adequate. Unfortunately the hospital is under a severe financial handicap, the present deficit in running it being nearly £30,000, in addition to which there are liabilities in respect of the building fund and other contingencies.

What was formerly the South Devon and East Cornwall Hospital was established in 1840, when the population of Plymouth was 35,000. The cost of the building, which

Prince of Wales's Hospital, Plymouth.

whom the responsibility for the management has rested from exercising a faith which has reflected itself in a progressive policy, the result being that the hospitals of Plymouth are among the best-equipped in the country.

The Prince of Wales's Hospital

Until recently there were three main hospitals, the largest being the South Devon and East Cornwall, the Royal Albert, and the Homoeopathic, but under a recent charter these have been amalgamated and are now known

as the Prince of Wales's Hospital. This sum being raised by voluntary contributions. There was at that time accommodation for twelve patients, and at the first annual meeting it was reported that twenty patients had been received. In due course the number of beds was increased, until in 1847 there were forty-two. Through the generosity of the Earl of Mount Edgcumbe wards were set apart for patients who were able to pay for their own maintenance, which was then apparently 10s. a week. In 1852 a new wing, erected at a cost of £1,050, gave an

The hospitals of the council are staffed in part by whole-time medical officers under the direction of the medical officer of health, and in part by part-time consultants, who are otherwise engaged in active practice in the city.

Plymouth Public Dispensary

The Plymouth Public Dispensary is 140 years old, work there having begun in 1798 at the Mayoralty House in Woolster Street, the dispensary being removed three months later to other quarters. It was in 1804 that a garden in Catherine Street was bought, and the present building was in due course erected on the site. The originator of the dispensary was Mr. Charles Younge, an eminent medical man, who left it £1,000 in 1807. An excellent portrait of this worthy by Northcote hangs in the Governors' room. It may be said that the South Devon and East Cornwall Hospital was an offshoot of this institution, and at one time the possibility of a union between the two was considered. Nothing came of the project, however, and the dispensary continues its beneficent work, the number of patients in the year ended September last being over 3,300, with total attendances of nearly 12,000.

Some records of the dispensary provide curious reading these days. For instance, the committee decided in 1799 that the medical officer be empowered to "order wine and porter occasionally for the patients," and two years later came to the conclusion that it was very desirable to extend the benefit of cow-pox inoculation, "which is now generally acknowledged to be a safe and effectual prevention of small-pox," to the poor. At a later date the committee held a special meeting to consider the expediency of taking some specific steps towards obtaining apparatus for dealing with suspended animation; further, it was only after ascertaining that the dispensary pump was beyond repair that the "town water was brought in." In 1832 the following committee minute is recorded: "A serious affection of the stomach and bowels be prevalent in the town and that, regarding it as a probable precursor of a more malignant disease, they had deemed it necessary to provide for such applications for medical aid from the dispensary without waiting for formal admission by ticket." A little later cholera broke out, and the dispenser was paid a guinea for additional work during the epidemic, the duration of which, however, is not stated. In 1800 it was considered "highly expedient that the establishment of this excellent institution should be annually commemorated by attending Divine service." Subscribers were accordingly invited to St. Andrew's Church for that purpose, an annual custom that prevailed for many years.

Money came from all sources. The Guardians of the Poor paid their first subscription of twelve guineas in 1809. Various sums from the Mayor represented fines, though upon whom imposed and for what offence there is no enlightenment; but one gentleman sent five guineas he had won as a bet because he regarded this to be "a weak method of supporting an argument." The dispensary also received a similar sum forfeited by two men "who had improperly secreted an anchor they had weighed"; and £1 came as a "part of an acknowledgment for improper conduct," the Mayor again being the medium for passing on the money. Mr. Toll's chimney caused a spot of bother. It fell and damaged the dispensary, leading to "sundry repairs," the cost of which was defrayed by the committee, the unfortunate Toll "being insolvent and unable to pay for the same."

In 1821 the facsimile of an instrument invented in Edinburgh and used there for extracting a double-barbed fish-hook from a youth's throat was "gratefully received." Leeches were apparently used in the treatment of patients, for another minute requests the medical officer "to give written orders, duly signed, for the supply of leeches, and that no leeches be paid for unless the order of the medical officer is produced."

The Plymouth Medical Society

The Plymouth Medical Society is one of the oldest in the provinces, having been inaugurated as far back as 1794. It is still very active. Originally the idea was presumably a close corporation, for the first rule laid down that it should "consist of no more than fifteen members, who are to meet on the Friday close to every full moon at 7 o'clock in the evening at the home of one of the members in rotation, where all business relative to the society shall be transacted." Of the two founders, Dr. Remmett and Samuel Fuge, the former was president till his death in 1828, and also the first honorary treasurer, secretary, and librarian. Truly he earned the title of "Father of the Society." In 1817 extraordinary members to the number of twelve were admitted as associates, but in 1826 members were unlimited. A reconstruction of the society followed in 1869 which, among other changes, made no distinction between members. Among the many distinguished members was Dr. Cookworthy—nephew of Cookworthy, of Plymouth china fame—who was secretary and treasurer for a long period. The society continues with even greater vigour its educational work for the profession, and possesses a valuable library at its headquarters in Beaumont House.

CONTROL OF RABIES IN PALESTINE

A feature of the annual report for 1936 of the Department of Health, Palestine, is the inclusion of three maps, showing respectively the Public Health Administrative Divisions, the incidence of hookworm as shown by the 1932-5 survey, and the stations of the Public Health Laboratory and Anti-Rabic Service.

Rabies constitutes a problem of considerable importance in Palestine. Anti-rabic vaccine, a modification of Semple's carbolized killed virus, has been manufactured at the Department's Central Institute in Jerusalem since 1923. By a wise policy of decentralization treatment is made readily available throughout the country, and no fewer than thirty-eight provincial health offices are supplied with adequate issues of vaccine. During the year under review 1,350 persons attended for specific treatment, and of these 1,280, or more than 94 per cent., reported within four days of being bitten. It is thus evident that the facilities for anti-rabic treatment are regarded with confidence and enthusiasm by the populace. Of the 1,350 who received treatment only one died of hydrophobia. The victim was a Palestinian Arab boy, aged 4, who was severely bitten in the right arm by a dog which ran away. Specific treatment was begun on the following day. Symptoms of hydrophobia developed thirty-three days after the bite, and nineteen after completion of treatment. Death occurred four days later. It is noteworthy that another child was bitten by the same dog on the same day; in this case the course of treatment was successful. Among untreated persons there were two deaths from hydrophobia. One case was a young Rumanian Jew, aged 16, who was slightly bitten on the hand by a dog in Oradia, Rumania, four months before he arrived in Palestine. The period of incubation was 241 days, the duration of the disease three days. The other case was a Palestinian Arab, a villager aged 35. He was bitten severely on the face by an unknown animal, possibly a jackal. Symptoms developed thirteen days later, and the sufferer died on the following day.

The importance of rabies control in Palestine is demonstrated by a table showing the number of animals destroyed during the year. The total figures are: dogs, 10,608; cats, 1,346; wild animals, mostly jackals and foxes, 1,301. The dog has been chiefly incriminated in the dissemination of rabies. Of eighty-seven cases of rabies notified, sixty occurred in dogs and eleven in cats. Of the 1,350 persons receiving treatment, 910 were bitten by dogs. Cats were incriminated to the number of 123, jackals 45, and ruminants 48; other animals included the fox, the mongoose, the rat, and the mouse.

assured of free maintenance and treatment by paying contributions equal to a penny for every pound earned in wages produces well over £20,000 yearly—a sum which, incidentally, represents the hospital's annual wages bill. The amalgamation of the Ear and Throat Hospital with the main hospital enabled the Governors to utilize that building as a nurses' home. Eleven years ago Mr. Arthur R. Cash, from the Norfolk and Norwich Hospital, was appointed general superintendent and secretary, and he has rendered, and continues to render, conspicuous service.

It was in 1934 that unification of the hospitals became an accomplished fact. Such a step has been fully justified, enabling the Governors the more efficiently to meet the public needs so far as the financial resources of the hospital permit. The Board of Management was fortunate in securing as its first chairman Dr. R. H. Wagner, who for many years was one of the leading practitioners of the city. Dr. Wagner still fills that responsible and arduous position, bringing to bear upon it not only wide medical experience but business acumen combined with a mind of catholic culture.

The hospital is recognized by the Conjoint Board, and medical students studying there are entitled to have the portion of the time so spent treated as the equivalent of passing a like period in a London hospital. In addition to the nurses' homes training schools are maintained. Working in conjunction with the hospital are the Pearn Convalescent Home, provided and endowed many years ago by a gentleman bearing that name, and another Home at Crownhill, near Plymouth, which is used as a recovery Home.

Dr. Colin D. Lindsay, President-Elect of the British Medical Association, retired from the post of senior honorary physician in May of last year, "after a long and honourable association with the hospital." To quote from the last annual report: "He was appointed honorary assistant physician to the South Devon and East Cornwall Hospital in January, 1913, reaching the senior staff in April, 1926. During twenty-four years he has rendered service of a high order, carrying out the duties of his office skilfully and ungrudgingly."

The Lockyer Street Section of the Prince of Wales's Hospital was originally the Homoeopathic Hospital, the inception of which was due to Dr. Field, who came to Plymouth in 1870 and opened a dispensary. A gift of £1,000 enabled a house in Union Street to be purchased, and it was opened for the reception of ten patients in 1884. Subsequently a house in Lockyer Street was purchased, and the hospital was transferred there in 1893, under the name of the Devon and Cornwall Homoeopathic Dispensary and Cottage Hospital. After a lapse of years the adjoining house was acquired and added to the institution, which five years earlier had changed its name to the Central Hospital, it having been decided by the governing body to provide general and universal medical as well as homoeopathic treatment. A well-known medical practitioner, Dr. Wilmot, was elected honorary physician in 1902. He served for twenty-three years, and on retirement became honorary consulting physician. Dr. Wilmot was president of the British Homoeopathic Congress when it met in Plymouth in 1930.

The Devonport Section of the Prince of Wales's Hospital was for many years the Royal Albert Hospital. It evolved from the Dock (Devonport's old name) and Stonehouse Public Dispensary, which, established in 1815, functioned for over half a century. The hospital was projected by Thomas Woolcombe, Joseph May, and Alfred Norman (the last-named prepared the plans), Miss Florence Nightingale being responsible for the arrangement of the wards. The memorial stone was laid in 1862 by the Earl of Mount Edgcumbe with impressive Masonic ceremony. The Government granted £3,500 towards "lock wards," then first instituted for the treatment of "certain women,"

and these functioned till, as the result of general agitation and after fierce controversy, the policy came to an end. The hospital, situated near the naval dockyards, has received good support from the men employed there. In the year before amalgamation sixty-one beds were available and the average number of patients resident daily was fifty; during the twelve months 988 in-patients were admitted, out-patients numbered 5,588, and total attendances were 36,000.

The Royal Eye Infirmary

Like the other hospitals the Royal Eye Infirmary had a small beginning and owed its inception to one who, impelled by what has aptly been termed the "civic spirit," wished to do something to alleviate suffering. This gentleman, Dr. John Butler, specialized in the treatment of the eyes, and after consulting medical men in London and several provincial centres opened a dispensary in 1822. The demands upon it were such that developments became imperative and larger premises were acquired in Millbay Road. On the site to-day stands a large hotel. In 1828 the name was changed to the Royal Plymouth Eye Infirmary, the Duke of Clarence (later King William IV) having become patron. For thirty-two years Dr. Butler treated sufferers, and it is computed that he cured or relieved over 30,000 persons. To mark his benevolence he was presented with a silver salver and a portrait of himself in 1854.

In commemoration of Queen Victoria's Diamond Jubilee a fund was inaugurated, and as a result the present spacious hospital, equipped to-day on the most modern lines, was erected at Mutley at a cost of £15,000. It is stated that up to the eve of its removal to Mutley about 80,000 persons had been treated at the Infirmary. In its last annual report the committee recorded that during the year the number of new patients who received treatment was 3,649, the number of attendances 11,591, and the number of operations performed 618. This was the second successive year that the figures exceeded those recorded for any other year since the foundation of the institution. The balance-sheet showed a healthy state of affairs, income being in excess of expenditure by £1,045. It is worth pointing out that the institution has some sound investments, dividends on which totalled just over £1,000.

Municipal Hospitals

Since the passage of the Act of 1929 the Plymouth City Council has established a Municipal Hospital, which is rapidly developing into a very important institution for the treatment of acute as well as chronic disease. The main hospital is situated at Greenbank, and consists of acute medical and surgical wards and wards for chronic diseases. A maternity block is projected, and other extensive additions are in the programme of the City Council. A new nurses' home was added recently, and is a very good example of what can be done in this respect.

On the site of the old isolation hospital in Mount Gold a modern and extremely well-equipped Orthopaedic Hospital has been erected, the buildings being on the single-floor system. In the same grounds are sited the wards for cases of acute pulmonary tuberculosis. The more chronic type is dealt with through the tuberculosis dispensary at Beaumont House and at the council's sanatorium at Didworthy, which is beautifully situated in the Avon valley. The Infectious Diseases Hospital stands in grounds at Swilly, in the neighbourhood of the council's housing estate; while at Blackadon, near Ivybridge, the council maintains a very fine Mental Hospital, with which are associated several farms for the employment of suitable types of patients. A new block for private and voluntary patients has recently been added to this. The hospital also is delightfully situated on a height, and commands one of the lovely views so characteristic of the scenery of Devon.

earlier studies on the subject are numerous. He will be remembered as the author of the idea that prontosil acts on streptococci by decapsulating them and of experiments that were said to show that it neutralizes streptococcal toxins. Levaditi now seems chiefly concerned to prove that prontosil and sulphanilamide do not act as such on bacteria at all but are both converted, probably by the reticulo-endothelial system, into some other and more active substance. The basis of this belief is the fact that the drug is ineffectual in experimental intraperitoneal infection if given by the same route. It saves life only when given by the mouth or parenterally; hence it is utilized primarily elsewhere than at the site of infection. His observations include elaborate studies of the cytology of the exudate in treated and untreated animals which are of much general interest, more particularly in exalting the defensive capacity of the macrophage and depreciating that of the polynuclear.

More illuminating perhaps than many pages of Levaditi's polemics is a simple experiment recently reported by Buttle.⁶ In mixtures of monkey blood, sulphanilamide, and streptococci, bacterial growth always proceeded for two hours and then ceased. If the blood had previously been freed from leucocytes the number of streptococci then remained stationary; in the presence of leucocytes the number fell almost to zero. This experiment surely shows that there are two effects—one purely bacteriostatic and one which might be described as opsonic. But in the divergent attitudes of the two distinguished observers previously quoted one thing is common: they do not accept the phenomena of bacterial destruction in such simple tube experiments as the whole explanation of what occurs in the body. This point is vital not only in theory but in the devising of means whereby laboratory experiment may perhaps guide the course of future therapeutic trials. With the number of already synthesized sulphonamide compounds running into three figures and the whole range of pathogenic micro-organisms awaiting their attack, some simple preliminary method of testing anti-microbial activity would be a godsend if its results were significant in relation to clinical effect. It is now claimed by Osgood⁷ that his method of observing the behaviour of bacteria in cultures of human marrow containing various concentrations of sulphanilamide will serve this purpose of preliminary trial. One of this author's principal conclusions is that sulphanilamide neutralizes streptococcus toxins, but his only evidence for it is absent or reduced haemolysis in cultures, and many anti-

septics which are useless therapeutically have this effect on streptococci *in vitro*. These experiments leave it uncertain whether haemolysin is neutralized or whether its formation is prevented, but an experiment was reported some time ago by Meyer⁸ in which the neutralization of pre-formed haemolysin appears to have been achieved with high concentrations of prontosil. This aspect of the matter needs fuller investigation.

HEALTH AT THE UNIVERSITIES

In the report of the British Medical Association's Committee on Physical Education⁹ it is noted that physical education is "conspicuous by its absence" in universities. With few exceptions "the universities make no provision for gymnastic training with or without apparatus. Facilities for games and athletics are provided, but a considerable proportion of undergraduates do not participate in this side of university life." Even with regard to university departments for the training of teachers it is said that "very little physical education is obtainable and many students take little part in games." The committee deplored this neglect, particularly in the training departments.

"A strong claim for the personal training could be made out on the ground of the benefit to the student's health and physical fitness and the consequent increased capacity to profit by the university course. Moreover, a knowledge of gymnastic training, games, and athletic sports, and a degree of skill in them, are of real professional value to teachers and an asset to their schools. . . . A satisfactory standard of physical education in senior and central schools is not to be expected so long as the university training departments as a whole continue to show a lamentable lack of interest in the subject."

It is now two years since that report was published, and these important pronouncements have perhaps not attracted so much attention as some other parts of the report. Their value as an initiative to reform in this field may, however, be stressed, and they are now strongly reinforced by the results of an inquiry conducted by the National Union of Students of the Universities and University Colleges of England and Wales and published in a pamphlet entitled *Student Health*.¹⁰ In an introductory section attention is called to the B.M.A. report and to other similar statements by individuals, as well as to a section on general health services in the last quinquennial report of the University Grants Committee—commented upon at the time in the columns of this *Journal*—in which the provision for physical training in the

SATURDAY MARCH 5 1938

THE MECHANISM OF THE NEW
CHEMOTHERAPY

The enormous expansion of chemotherapy in bacterial infections now being witnessed is proceeding largely on empirical lines. It is true that curative experiments in animals justify much of it, but these experiments are themselves empirical, and no one can yet begin to explain why quite closely related bacteria such as haemolytic and non-haemolytic streptococci exhibit widely different degrees of susceptibility, or how among the many new compounds now being synthesized slight differences in chemical structure so profoundly affect therapeutic activity. The number of these compounds is constantly expanding; so also is that of the infections in which they are said to be useful. Experimental work by Rich and Fillis¹ of the Johns Hopkins Medical School shows that sulphanilamide can exert a "striking inhibitory effect" on the development of tuberculosis in the guinea-pig. Two recent publications, though unimpressive in the weight of their evidence, are portentous if they are to be accorded any significance at all. According to de Léon² prontosil will cure malaria, and Rosenthal, Wooley, and Bauer³ have demonstrated a protective action by this drug against lymphocytic chorio-meningitis in mice, though they also record negative results in protection tests against the viruses of influenza and the St. Louis type of encephalitis. If to a number of bacterial infections we are now to add virus diseases and protozoal infections as profitable subjects of therapeutic study, the amount and complexity of the work yet to be done if present methods have to be followed defy the imagination.

It is almost a relief to turn from this welter of therapeutic experiment to a reconsideration of first principles. Two important recent papers have reverted to the original problem of how prontosil acts on streptococci in the body; if this question could be fully answered it might well afford an insight into the wider problem and provide methods

of attacking it which would shorten its investigation by years. Belief on this specific question has passed through two stages, and may now perhaps be said to be entering upon a third. The first was purely agnostic. Prontosil had been found to cure mice infected with haemolytic streptococci, and this action was providentially paralleled in the human patient. The drug was almost without any demonstrable antiseptic action *in vitro*; therefore its effect in the body must be exerted indirectly by some unknown mechanism. The second stage was ushered in by the assertion of Tréfouel, Nitti, and Bovet that prontosil is broken down in the body, liberating the substance we now know as sulphanilamide. The work of Colebrook, Buttle, and others in England then showed that sulphanilamide, in contrast to prontosil, is bactericidal even in extreme dilution for small numbers of streptococci, and since in the average case of septicaemia the numbers of cocci in the blood are small it was reasonable to suppose that they were directly destroyed in the infected body. These observations led to the partial abandonment of prontosil and the substitution of sulphanilamide in therapeutics, as well as to a wide exploration of the possibilities of other related compounds. This simple explanation has never been universally accepted, and the objections to it are now marshalled by Domagk himself⁴ in a general review of the work which his discovery initiated.

Domagk does not believe either that prontosil is inactive in the body until it is split up or that its effect is simply that of an antiseptic. Of several reasons which he gives two carry more weight than the rest: the fact that the destruction of streptococci by sulphanilamide *in vivo* is more efficient in blood than in lifeless media, arguing that phagocytosis plays an essential part; and the discrepancy among different compounds of this nature between activity *in vitro* and *in vivo*, some which are highly antiseptic in the test tube being therapeutically valueless. As a further reason he adduces the variability of effect in different animals: if a certain concentration in the body fluids is all that is needed simply to kill bacteria, why should this in some cases bring about a cure in rabbits and not in mice? Domagk seems to have no very positive substitute to offer for what we may call the English hypothesis, but his attitude is broadly that prontosil makes streptococci susceptible to attack by the normal bodily defences; the appearance of degenerate cocci in treated animals is held, not very convincingly, to indicate some change rendering them vulnerable. The second contribution to this problem is that of Levaditi,⁵ whose

¹ Johns Hopk. Hosp. Bull., 1938, 62, 77.² Publ. Hlth. Rep., Wash., 1937, 52, 1460.³ Ibid., p. 1211.⁴ Z. klin. Med., 1937, 132, 775.⁵ Monographies de l'Institut Alfred Fournier, No. 5, Paris, 1937.

male hormone appear to be antagonistic in certain circumstances. The latter is now being employed in cases of chronic mastitis and favourable reports are beginning to appear.

SPONTANEOUS RECOVERY FROM CANCER

The frequency of spontaneous cure in cancer has been placed at one case in 100,000. In fully authenticated cases a primary growth has been quite incompletely removed or merely subjected to biopsy and has nevertheless later disappeared, necropsy following death from another cause revealing no trace of the growth. Mr. Digby Chamberlain's case, described on page 508, involves a slight element of doubt, since the primary growth was excised, and the nature of both the enlarged glands which were seen and the liver nodule which was felt cannot be considered absolutely certain. The subject of spontaneous recovery from cancer has recently been reviewed by Touraine and Duperrat,¹ who discuss the circumstances in which it takes place and possible explanations of it. Of many factors which have been supposed to be responsible fever is most often mentioned, while infection of the growth, or the treatment of an infective condition, such as syphilis, in which the growth arose, has also been given credit for its regression. If these influences play any part they can only have this effect very exceptionally: infected growths frequently spread rapidly, and hyperpyrexia has been found unavailing in the treatment of growths in animals, even when carried to a point which would be unjustifiably dangerous in man. Although high temperatures are no more lethal to cancer cells than to the rest of the body, it remains possible that fever or some other disturbance may exceptionally cause a metabolic change inimical to the cancer cell. This metabolic hypothesis, completely vague though it is, appears to be one of the two chief possibilities, and it can go no further than to suggest that in some way the nutrition of the growth is interfered with. The other assumes the development of a humoral immunity, or at least a specific attack on the growth. Leucocytic infiltration at the margin, which is undoubtedly more pronounced when the growth rate is slow, and particularly so after successful irradiation, lends support to the idea that the body is capable of attacking a growth by the same means as are used against foreign invaders. The existence of a specific antibody to the cancer cell has been both asserted and questioned, and the part played by humoral immunity in cancer remains a matter of great doubt and difficulty. Regression occurs frequently in transplanted animal tumours; in some indeed it is the rule, and the contrast between the behaviour of these transplanted tumours and spontaneous growths is so marked that what is true of one may well not apply at all to the other. There is one encouraging aspect of this subject: the mere fact that human tumours ever regress, however rarely, suggests that some mechanism exists by which the same result could more often be brought about, and this may yet be discovered.

PHARMACOLOGICAL RESEARCH

The annual report of research work carried out at the College of the Pharmaceutical Society in 1937 shows that this college is actively continuing its work on the advancement of knowledge regarding the properties of drugs. The Department of Pharmaceutical Chemistry has investigated the chemotherapeutic actions of a series of acridine compounds and has found certain classes with a bactericidal activity greater than that of acriflavine. The Nutrition Department has continued its work on the testing of vitamin preparations, and also has carried out an interesting research on the effect of calcium-poor diets on the ash content of bones of rats, which has led to the conclusion that a child receiving an ordinary "poorer-class" diet and drinking London water would receive only about half the quantity of calcium necessary for normal bone development. The Department of Pharmacology has continued interesting researches on the standardization of the adrenal cortex preparations by their action in prolonging the life of adrenalectomized drakes. The testes of drakes have a big seasonal variation in size (3 grammes to 78 grammes) and a close correlation has been found between the effective dose of cortical hormone and the size of the testes. This discovery is of particular interest on account of the well-known effect of cortical tumours in producing sexual precocity. The report contains accounts of many other important researches, and it is of interest to note that the laboratories have given hospitality to a number of foreign workers. The year under review has seen important changes in the staff of these laboratories, and it will not be long before they move to new quarters in Brunswick Square. We wish them all success under the new conditions.

UNUSUAL FACTORS IN RICKETS

Although the majority of children with rickets are readily cured by adequate doses of cod-liver oil, types resistant to therapy occur from time to time. Such a case is fully reported by F. Albright, A. M. Butler, and E. Bloomberg,¹ who recount observations extending over fourteen years upon a boy now aged 16. He was not suffering from coeliac disease or from renal disease, two recognized causes of resistant rickets, but at the age of 2 he showed clinical and radiographical evidence of rickets, which failed to improve after nearly two years' treatment with cod-liver oil (3 drachms daily) and sunlight. The first problem the authors discuss is concerned with the abnormal condition of the bones—was it true rickets? Histological examination of a portion of the sternum removed for biopsy, the x-ray appearances, and investigation of the metabolism of calcium and phosphorus proved that the bony changes were undoubtedly those of rickets. The part played by the parathyroids had also to be considered, as it is now accepted that there is some degree of hyperparathyroidism in rickets. At operation only three of the glands were found and none was enlarged, although there was definite hyperplasia in one removed for

universities and of some form of student insurance against illness is advocated. Pronouncements such as these have no doubt produced some sort of intellectual conviction in university and associated circles, but apparently more is still needed to overcome what the N.U.S. report calls "the immense inertia of the established system," and to translate conviction into action.

To establish and recapitulate the facts demonstrating this need for action requires a few pages only. The report then goes on to give a valuable review of the university health services in the United States of America, in Canada, in Germany, and in Sweden, and to state the nature of the relatively little provision made for medical and health services in British universities at the present time. Then follow a short summary of recommendations previously made concerning such services and the establishment or improvement of physical education at universities, and proposals for a minimum policy on these matters made by the Committee of the National Union of Students itself. The needs and aims are really threefold: an insurance or contract scheme for the medical examination of students and their treatment and care in case of illness, such scheme to have regard to their economic position; the organization of systematic courses in physical training, together with the provision of suitable facilities, open to all the students and so designed as to attract and help those who merely want to keep themselves fit and improve their condition, whatever their future walk of life may be; the establishment of courses of a more technical character for those who will be responsible for physical education in the schools or as organizers of physical recreative training under the direction of local authorities. It is with the first two of these objects that the report is mainly concerned, but the third has become at the present time an important function of institutions of university rank. Again, there are at least three points which should be borne in mind as essential to the success of these developments. The object is to assist the student to better health and physical condition where he needs this, not at all to debar an unfit student from a university career. There should be considerable freedom of choice among activities, and not too much insistence on particular requirements. Under a director of physical education the general management, particularly of games, should continue to be exercised by the students themselves. The proposals of the N.U.S. report are on these lines, and the details given will be found helpful to all those who have responsibilities in this field or who are in a position to hasten the action which is more and more urgently needed.

ENDOCRINE FACTORS IN BREAST TUMOURS

That the mammary gland is one of the effector organs of the endocrine system is an observation not only of physiological interest but of pathological importance. The variation of response of different species to the hormones concerned has made it difficult to define the function of each particular factor, but the available evidence suggests that oestrin is responsible for the development and ramification of the ducts and for the proliferation of the periductal connective tissue, while progesterone opens up the terminal acini, and the lactogenic hormone of the anterior pituitary stimulates the secretion of milk. The definition of the part played by oestrin is substantiated in our present issue (p. 499) by the interesting study of Drs. Geschickter and Dean Lewis of cases of fibro-adenoma of the breast observed during pregnancy and lactation. The rapid increase in size of these growths during pregnancy is due to development of duct epithelium and the surrounding fibrous tissue. The response of the tumour to the increased concentration of oestrin during pregnancy depends on its previous state of development. In some cases the opening up of peripheral tubules with coincident proliferation of connective tissue leads to rapid enlargement of the tumour. In others already submitted to prolonged oestrogenic stimulation there is an exaggeration of the epithelial and fibrous proliferation, with blockage of ducts, formation of cysts, and epithelial overgrowth, without encapsulation—very closely simulating malignancy. In a third type intensive oestrogenic stimulation has led to fibrosis and hyalinization, so that the increased concentrations of oestrin in pregnancy are without effect on the tumour. Such observations offer fresh support for the principle that the response of a tissue to an endocrine stimulus depends not only on the concentration of the stimulating hormone but also on the sensitiveness of the tissue, which is determined by its structural and functional state at the time the stimulus is applied. This principle of the susceptibility of the tissue is probably of fundamental importance in determining the degree of response to endocrine stimulation. The females of certain strains of mice are highly susceptible to spontaneous mammary cancer; others are resistant to cancer. The administration of oestrin to the males of cancer-susceptible strains induces the development of mammary cancer in a percentage equivalent to that attained by the females, suggesting that these strains respond easily to oestrin and that in such strains oestrin, by virtue of intensive activity, may become carcinogenic. Fortunately the human breast appears to be more resistant to stimulation by oestrin, and it is improbable that the concentration of oestrin found at any time in the blood stream naturally or as the result of treatment can so activate the breast as to form a basis for malignant changes. The demonstration that oestrin may be responsible for innocent changes in the breast such as fibro-adenoma and cystic mastitis, however, suggests that the giving of some antagonist to oestrogenic activity may be a possible line of treatment for such conditions. Progesterone and the

section. Post-operative chemical changes in the blood favoured the view that a secondary hyperparathyroidism was probably present in this case. Thinking that the absorption of vitamin D might be at fault, the authors injected a crystalline preparation intravenously, but this had no beneficial effect. Next the oral dose of vitamin D was pushed up to extreme limits (1,500,000 U.S.P. units of vitamin D daily, equivalent to 15 litres of cod-liver oil), and at last there was some x-ray evidence of healing. It is pointed out that most careful and frequent examinations of the blood must be made with such dosage to avoid the calcifying effects of hyper-vitaminosis. In such a patient as described above there is some intrinsic resistance to the action of vitamin D, but the aetiology of the resistant rickets is at present unknown. A possible biochemical factor in certain cases is suggested by B. Hamilton and M. M. Dewar.² They found that when sodium citrate was added to a rachitogenic diet in the proportion of 0.4 mol to each kilogramme of diet it prevented the development of rickets in rats, and a similar effect was produced by sodium tartrate and sodium bitartrate in the proportion of 0.8 mol to each kilogramme of diet. Citric and tartaric acids also had an antirachitic effect, although it was less marked than that of sodium salts. Further, the acids and the salts promoted healing when administered to rachitic animals. Various factors are probably concerned with these effects. For example, the hydrogen ion concentration of the gastro-intestinal contents is probably increased by the acids and thus the solubility of the calcium phosphate compounds is enhanced. Changes in the acid-base metabolism of the body may also come into the picture, and in this connexion the results reported by G. Graham and W. G. Oakley³ of the effects of administering alkalis in cases of renal rickets are of interest. Despite the downward progress of patients with this disease, massive doses of alkalis effected some temporary control.

POLIOMYELITIS IN NEW ZEALAND, 1936-7

The annual report of the New Zealand Department of Health for the year ended March 31, 1937, records a slight rise in the death rate, which was 8.75 per thousand. Infant mortality was the lowest ever recorded—namely, 30.96 per thousand live births. There was also a welcome rise in the birth rate and a substantial decline in maternal mortality. The latter was 3.70 per thousand live births. Deaths from septic abortions are included in this figure. In 1924, when an active campaign for the promotion of maternal welfare was first inaugurated, the maternal death rate was 5.0. All the above statistics are exclusive of the Maori population. The chief epidemiological feature of the year under review was an outbreak of acute poliomyelitis, which occurred in Dunedin during December, 1936. In the first three weeks notifications were 2, 16, and 40 respectively. The public were informed immediately and picture-theatre proprietors co-operated by voluntarily excluding children from their

establishments through the whole of New Zealand. All schools were closed. The authorities sought the collaboration of representatives of the New Zealand Branch of the British Medical Association. As a result in each of the four main centres a practitioner with special knowledge of poliomyelitis and its treatment was appointed whose experience was available for his colleagues in consultation. The great majority of the cases were treated in hospital. Nevertheless, despite all precautions the disease spread through the whole of New Zealand during the first quarter of 1937. Practically no district escaped. The peak of the epidemic was reached in April, when there were 246 cases. During the period from December, 1936, to the end of June, 1937, there were 819 cases, including 43 Maoris: the deaths numbered 39. It is stated that a fuller account of the epidemic will be published in the next annual report.

URINARY IODINE IN HYPERTHYROIDISM

Iodine is excreted through the kidneys, sweat glands, salivary glands, and in the bile. The amount excreted depends chiefly on the intake, and this is borne out by the striking diminution in urinary iodine among the population in regions of endemic goitre, where the environmental iodine is low. In hyperthyroidism, however, where the intake is not in excess of normal, the urinary excretion of iodine is increased, as the patient is in a state of negative iodine balance through increased production of the iodine-containing hormone of the thyroid gland and consequent depletion of the iodine stores. G. M. Curtis and I. D. Puppel¹ have investigated the urinary excretion of iodine in forty patients with hyperthyroidism. They found that the average urinary excretion was 184 γ of iodine per day, which was between three and four times greater than that of normal subjects, their average figure for these being 51 γ of iodine per day. The variability of the daily urinary excretion of iodine in hyperthyroidism was considerable, ranging on an average from 30 to 593 γ , and these variations corresponded to the variations of the clinical features of the disease. They consider, however, that a normal urinary excretion of iodine in hyperthyroidism does not necessarily indicate that there is not a pathologically increased loss of the body iodine, as there may be a greater output of iodine through other channels, or there may be retention of iodine through renal insufficiency or a depletion of available utilisable iodine. There is no evidence, however, that their patients had any impairment of renal function. Nevertheless the authors present evidence in favour of at least partial depletion of the iodine stores, such as an increased retention of iodine immediately after its administration. This depletion of the iodine stores in the absence of a sufficient intake may explain some of the spontaneous remissions of toxic goitre. Determinations of the blood and urinary iodine would be of considerable diagnostic importance in those cases of neuro-circulatory asthenia in which the clinical features simulate borderline hyperthyroidism.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

THE TREATMENT OF JOINT SPRAINS AND STRAINS

BY

R. C. ELMSLIE, M.S., F.R.C.S.

The terms "sprain" and "strain" cover a variety of injuries to joints in which there is no evidence of a gross fracture or dislocation. As a rule when a definite injury—a fracture, a dislocation, a complete rupture of an important ligament, or a displacement of a semilunar cartilage, etc.—has been found, the fact that an exact diagnosis has been made takes the case out of the category of sprains or strains. Therefore in all these cases of minor injuries of joints the first thing to aim at is an exact diagnosis. It is not uncommon to find that a joint injury which has resulted in an effusion is diagnosed as a case of traumatic synovitis. There are grave objections to this diagnosis because it is apt to lead to slack methods and to a failure to discover exactly what has happened. We ought to try to determine what has been the nature of the trauma and exactly what lesion has been produced in the joint.

Classification of Ligaments

From the practical point of view the ligaments of joints may be divided into three classes:

1. Those consisting of a simple thickening of the capsule which cannot be defined exactly by dissection except in an artificial manner. As is the case with the joint capsule as a whole, the attachment of these ligaments to bone is also indefinite; the fibrous tissue of the ligament is continuous with that of the periosteum beyond, which can be stripped up if the ligament is artificially lifted. The internal lateral ligaments of the knee and ankle, and in fact the majority of ligaments of joints, fall into this category.

2. Extracapsular bands which stand out, when dissected, as isolated structures. Such are the external lateral ligament of the knee and the middle and posterior fasciculi of the external lateral ligament of the ankle.

3. Intra-articular bands, such as the crucial ligaments of the knee, the ligamentum teres of the hip, and the intra-articular fibro-cartilage of the sterno-clavicular joint.

Injuries of Capsular Ligaments

Ligaments of the first category are not likely to be ruptured completely unless the capsule is itself extensively torn by such a force as may produce a dislocation of the joint. In a sprain the injury to the ligament is partial, and it is most likely to occur at the point of attachment to the bone. The joint cannot be sprung open, and no hypermobility or instability of the joint results. For example, in the case of the internal lateral ligament of the knee-joint forced abduction of the tibia on the femur strains the point of attachment of the ligament to the internal condyle of the femur. This point is tender, and some swelling and possibly discoloration appear over it. But the knee does not become hypermobile, and cannot be sprung open on the inner side by forcing the tibia outwards. In fact, mobility of the joint is restricted by pain, and the knee is generally held in a position of slight flexion because in this position the ligament is relaxed and therefore less painful.

The common sprain of the ankle is an injury of the anterior fasciculus of the external lateral ligament, produced by twisting the foot inwards while it is in a position of slight plantar flexion. Either the substance of the ligament or its attachment to the neck of the astragalus may be injured, and the tender spot varies accordingly. But the movement of the foot, particularly inversion, is diminished by pain. There is no hypermobility.

Sometimes in injuries of this class the strain upon the ligamentous attachment pulls off a portion of the bone, or it may, as already mentioned, pull up the periosteum for a short distance beyond the actual ligamentous attachment. The detachment of a fragment of bone constitutes a sprain fracture. These injuries occur frequently and characteristically in the interphalangeal joints and metacarpo-phalangeal joints of the hand, where a lateral or antero-posterior strain may either damage the point of attachment of the lateral or anterior ligaments or else may tear off a tiny fragment of bone from the margin of the phalanx or metacarpal head. On the posterior surface such injuries are uncommon because flexion of the joints is free; the terminal joint is an exception, but there the extensor tendon is commonly damaged and not the joint ligament. The tendon may rupture or tear off a fragment of the phalanx.

Sprain fractures also occur at the attachment of the internal lateral ligament of the knee to the femur, the usual site of an injury to this ligament. A fragment of bone may be torn off at the time of the injury and be shown by a radiograph; or the bony fragment may only appear later and be due to pulling up of the periosteum. In the latter case the bone may be high up on the condyle and not apparently at the site of attachment of the ligament. This fact has led to the naming of this condition Stieda-Pellegrini disease, in the belief that it is not due to injury of the ligament at all. This seems to be a quite unnecessary refinement. Sprain fractures also occur in a more gross and obvious form, as, for example, when the internal epicondyle of the humerus is pulled off by an abduction strain of the elbow and in fracture of the great tuberosity of the humerus.

Injury of Intra- or Extra-articular Bands

Rupture of such ligaments as the external lateral ligament of the knee, the crucial ligaments, and the middle fasciculus of the external lateral ligament of the ankle gives rise to instability of the joint which is immediate. Thus, in the knee if the external lateral ligament is ruptured the knee can be sprung inwards and opened up on the outer side; if the crucial ligaments are ruptured, even incompletely, excessive antero-posterior mobility of the joint is present. In the case of the ankle rupture of the middle fasciculus of the external lateral ligament allows excessive inversion of the foot, the astragalus tilting in its socket—a fact which can be demonstrated by taking a radiograph in full inversion. The posterior fasciculus of this ligament does not appear to be often injured, but when strained it may pull off the posterior tubercle of the astragalus, to which it is attached: this tubercle sometimes occurs as a separate bone (os trigonum). Such an injury leads to chronic pain and

ment should on no account be forced. The strapping should only be left off and increased use encouraged when the swelling and tenderness subside. This is likely to take at least six weeks, and may take several months, especially if injudicious use and movement have been allowed early. In the case of the knee-joint the use of a compression bandage with gentle walking exercise and some faradic treatment of the quadriceps muscle will suffice in the slighter injuries. In severe cases, in any region, when a radiograph shows ossification in the attachment of the ligament or beyond it the joint should be immobilized on a splint in an easy position just short of full extension until all pain and tenderness have disappeared, and movement then restored by gentle persuasive methods and without the use of force.

Treatment of Sprains which Render a Joint Unstable

These include ruptures of important ligaments and the cases of sprain fracture in which an important ligamentous or muscular attachment has been damaged—for example, fracture of the head of the fibula, the spine of the tibia, the internal epicondyle of the humerus, the attachment of the long extensor of the terminal phalanx of the finger, etc. The treatment of these injuries is really a part of major surgery and in many cases operation is advisable, but the recognition of the nature of the injury and its immediate treatment are important. The joint should be at once immobilized on a splint or, better, in plaster-of-Paris in a position in which the ligament affected is relaxed, and if there is difficulty in securing the position an anaesthetic should be given. Drop-finger due to damage to the extensor tendon should be splinted in hyperextension. Rupture of the middle fasciculus of the external lateral ligament of the ankle requires fixation in plaster with the foot at a right angle and everted. Rupture of the external lateral ligament of the knee-joint or fracture of the head of the fibula should be treated by plaster with the knee extended and the tibia forced outwards. Rupture of the crucial ligaments or fracture of the tibial spine requires fixation with the knee fully extended; in the latter case an anaesthetic is necessary in order to secure this position.

In the case of fracture of the internal epicondyle of the humerus operative fixation is essential because the fragment is pulled down by the pronator-flexor group of muscles. In all this group of cases the necessary surgical treatment by fixation support, etc., and possibly operation, can be facilitated by early diagnosis and correct fixation; in fact, in many cases the need for operative treatment may thus be avoided.

The third International Cancer Congress under the auspices of the International Union against Cancer will be held in the United States, September 11 to 16, 1939, at the Haddon Hall Hotel, Atlantic City, New Jersey. The president of the congress is Professor Francis Carter Wood, Director of the Institute of Cancer Research of Columbia University, New York City; Dr. Donald S. Childs of Syracuse, New York, is the secretary-treasurer; and Dr. A. L. Loomis Bell of Long Island College Hospital, Brooklyn, New York, is in charge of transportation and exhibits. The proposed sections are as follows: general research; biophysics; genetics; general pathology of cancer; surgery of cancer; radiological diagnosis of cancer; radiotherapy of cancer; statistics; and education. The membership fee is 15 dollars. All inquiries should be addressed to the Institute of Cancer Research, 1145, Amsterdam Avenue, New York, N.Y.

DIABETES AND ITS TREATMENT

LETTSONIAN LECTURES BY DR. GEORGE GRAHAM

The first of the three Lettsomian Lectures under the auspices of the Medical Society of London was delivered on February 21 by Dr. GEORGE GRAHAM, who took as his general subject a survey of the changes and results of treatment of diabetes in the last fifteen years.

Dr. Graham began by remarking that Lettsom apparently never addressed the society on any subject connected with diabetes, although in his time the presence of sugar in the urine had been demonstrated. Lettsomian Lectures on diabetes, however, had been delivered in 1860 and again in 1912. During the twenty years before the introduction of insulin diabetes was regarded as a very serious disease, and it was generally held that patients did not live for more than two years. That was not quite true, though certainly the majority did not live very long. The fasting treatment had helped a certain number, and it had been possible sometimes to stop a patient from passing sugar.

It was now a common contention among anti-vivisectionists that insulin was discredited because since its introduction the deaths from diabetes had gone up. This was true, though the statement unqualified contained a great fallacy. The lecturer showed a number of graphs indicating the death rate in England and Wales during the present century. One curious point brought out was that there were formerly always more men than women in the mortality tables of diabetes, but since the war this position had been reversed, and for many years past far more women than men had died of the disease. There was also a mysterious drop in the figures during the war years. It was suggested that this was due to dietary restrictions imposed by the war, but possibly in the absence of many doctors abroad patients were not examined as carefully as at other times, and deaths were attributed to other causes.

Deaths from Diabetes

The answer to the anti-vivisectionist was evident when the figures came to be examined for each decade of life. During the last fifteen years the deaths from diabetes for the age period 6-15 showed a 34 per cent. decrease for both sexes; for the age period 16-25 also a decrease—29 per cent. in the case of females and 41 per cent. in the case of males. A decrease of similar extent was recorded in the two following age groups, covering the period 26-45. In the age period 46-55, while there was still a decrease in the number of deaths of males, though of smaller extent than in the earlier periods, there was actually an increase in the number of deaths of females, and for the later age periods there was an increase in the death rate for both sexes, specially marked in the case of women.

During the period covered by the statistics the number of persons of 70 years of age and over per 10,000 of the population of England and Wales had gone up from 297 in 1911 to 344 in 1921, 426 in 1931, and 455 in 1934. Thus there were many more old people alive, and because people were living longer they were more liable to those diseases, diabetes being one, which their shorter-lived predecessors had escaped, having died probably of some disease more frequently attacking the young and early middle-aged. A further factor which had to be remembered in studying the figures was that in the later years of the period under survey doctors were more careful with regard to the examination of the urine, not only for albumin but for sugar. There had also been a change in the practice of death certification, and if pneumonia or bronchitis was the immediate cause of death and diabetes a contributory cause, the latter as well as the former would be mentioned on the certificate.

swelling behind the ankle on the inner side, which may persist until the separate piece of bone has been removed.

This last injury is, again, an example of a sprain fracture. Other examples occur—for example, the external lateral ligament of the knee may pull off a fragment of the head of the fibula, or the anterior crucial ligament may pull up the mesial spine of the tibia.

Injuries of Muscles and Bones in the Neighbourhood of a Joint

In investigating a case of supposed joint sprain or strain it must not be forgotten that the injury may really be one of a muscle, tendon, or bone. For example, forced inversion of the foot may sprain the anterior fasciculus of the external lateral ligament or it may rupture the middle fasciculus, but it may cause an oblique crack through the external malleolus of the fibula; or the tension on the peroneus brevis muscle may pull off the base of the fifth metatarsal bone (Jones's fracture) or pull some of the muscle fibres off its origin from the fibula. These injuries are disclosed by the exact position of the point of maximum tenderness, and in the first two cases are confirmed by radiographs. After forced dorsiflexion of the foot the calf muscles and tendo Achillis must be carefully examined: rupture of the tendon may easily be overlooked if much effusion is present. In young persons an incomplete injury in the neighbourhood of the epiphyseal bone should be borne in mind, particularly in the case of the hip-joint.

Exact Diagnosis

The multiplicity of the injuries which may be present in a case of strain of a joint would seem at first to make diagnosis a rather formidable task, but with care this should not be difficult. If possible the exact mode of injury should be determined; this helps by showing what structures were put on the stretch. When the examination takes place after a considerable effusion has formed the latter may to some extent mask the symptoms, but there should be no hesitation about feeling firmly into this swelling, particularly over important tendons such as the tendo Achillis and the tendon of the quadriceps. The site of maximum tenderness to pressure is important. It may be over the ligament or its attachment to a bone; if the latter, and if the tenderness is considerable, a sprain fracture may be suspected and a radiograph should be taken. If the point of tenderness is over the shaft of the bone a radiograph is essential in order that a fracture may be excluded. The mobility of the joint is important: hypermobility denotes complete rupture of some important structure. Limitation of mobility—without, however, complete blocking of movement—is the rule in the ordinary less severe sprain. The ideal would be to x-ray every case of joint sprain, but this may not be possible or practicable. A radiograph is essential:

1. When the maximum tenderness is over the shaft of a bone.
2. When the tenderness is over the point of attachment of an important ligament or tendon.
3. When movement of the joint appears to be mechanically blocked—for example, when extension of the knee-joint is blocked.
4. It is wise in the case of all severe sprains in children and adolescents because of the risk of bone injury. This applies especially to the hip-joint.

When other injuries have been separated those which are properly classified as sprains of joints may for purposes of treatment be divided into three groups: simple sprains; sprain fractures; and sprains which render a joint unstable.

Treatment of Simple Sprains

In treating a simple sprain of a ligament which forms part of the capsule of the joint and which is incompletely ruptured the first step is to prevent or limit effusion. This is best done by firm elastic pressure. For example, if an ordinary sprain of the ankle is seen within half an hour the site of injury may be wrapped in a complete covering of thick cotton-wool extending from the metatarsal heads to the middle of the leg and bandaged firmly from below upwards over this with a domette bandage, which should not extend beyond the cotton-wool. Some nervous patients will not tolerate this pressure; in these cases a cooling lotion, such as *lotio plumbi c. opio*, should be applied. In either case twenty-four hours' rest should be allowed. At the end of that time the bandage may be removed and the joint re-examined to confirm the diagnosis. If a radiograph is considered necessary it should be taken and bone injury thus excluded. The joint should then be firmly bound with an adhesive bandage of the elastoplast type, and the patient encouraged to begin use of the limb. In the case of the ankle a shoe should be worn if it can be got on, and the patient should walk with the help of a stick but not with crutches. He should be told to keep the foot under him and walk in as natural a manner as possible, allowing slight movements of the ankle-joint. In the case of the knee and elbow it is more comfortable to retain the compression bandage over cotton-wool, as the free range of movement of these joints is apt to lead to soreness of the skin under adhesive strapping.

At the end of a week the strapping is removed and is replaced by a simple crêpe bandage, and massage and movements are started. The masseur should be instructed first to get rid of the effusion, then to help all active movements through as full a range as possible, and to follow on with exercises in normal use. In the case of the ankle the patient must be encouraged to walk with a natural heel-and-toe movement, be given tiptoe exercises with support, and be persuaded to invert, evert, and dorsiflex the foot through a normal range. Finally, in the later stages of treatment movements which are incomplete must be forced gently until they are complete. If even a little restriction of dorsiflexion, plantar flexion, or inversion of the foot remains there may be persistent discomfort and a tendency to sprain the ankle again. Some nervous patients will not walk early upon a sprained ankle. In such a case it is better to retain the compression bandage and trust to the persuasive powers of a good masseur.

Treatment of Sprain Fractures

Sprains in which a small portion of bone has been torn off and those in which the periosteum has been lifted do not do well on treatment by the methods described above. There is a tendency to the production of a chronic painful thickening with limited movement. This applies to most sprains of the finger- and toe-joints and to sprains of the internal lateral ligament of the knee. These cases should be strapped up securely from the start and only a limited range of movement allowed; massage should not be given over the injured regions, and move-

Reference is made in the report to representations made at the inquiry that it would be of great advantage in dealing with an epidemic of this kind if there were means of securing closer contact and more ready communication between the medical officer of health and the general body of practitioners, so that all the information available from time to time as to symptoms and possible causes could be pooled and distributed. While recognizing that the sole responsibility for dealing with an outbreak must, as the report emphasizes, rest with the medical officer of health, the Minister, as he has previously stated in Parliament and elsewhere, considers it important that all practicable steps should be taken to secure the effective co-operation of local practitioners in this as well as in other matters with which the medical profession, as such, is concerned.

The Minister appreciates the importance which the Corporation doubtless attach to bringing the water from Addington well back into supply at an early date subject to necessary safeguards, and he does not dissent from the conclusion in the report that, with due attention to the gathering ground and suitable chlorination, there is no reason why the Addington well should not provide a perfectly healthy drinking water. The arrangements to be made for the treatment of the water are matters on which the Corporation will no doubt seek expert advice, and the Minister understands that they have already appointed consultants for this purpose. In this connexion the Council will no doubt pay particular attention to the view expressed by Mr. Murphy on the evidence submitted, that analysis of the water from the Corporation's chalk wells should be made more frequently than has been the practice in the past.

In addition to the general and fundamental need for improved co-ordination of the work of the committees and officers of the Council, and to the particular points to which I have referred above, the report deals with a number of other matters which merit, and will doubtless receive, attention. The Minister will be glad to learn from the Corporation at an early date the result of their consideration of the issues raised and to be informed generally of the action to be taken in the light of the report. If the Corporation so desire the Minister would be happy to arrange for his officers to discuss with them and their advisers any points arising on which it is thought they can be of assistance.

I am, Sir,

Your obedient servant.

GEORGE CHRYSTAL.

Reports of Societies

MINERAL SALTS IN THERAPY

At a meeting of the Section of Medicine of the Royal Society of Medicine on February 22, Dr. H. LETHEBY TIDY, presiding, a discussion took place on mineral salts in therapy.

Rationale of Sodium Therapy

Dr. R. A. McCANCE of the biochemical department, King's College Hospital, said that about 60 per cent. of the body was water. Roughly two-thirds of this was in the body cells; the remaining one-third—in the blood, lymph, cerebrospinal fluid, and intercellular spaces—constituted what were conveniently termed the extracellular fluids. Recent work suggested that the osmotic pressure of the cellular fluids was roughly equal to that of the extracellular, but whereas the bulk of the cellular osmotic pressure was due to potassium ions, that of the extracellular fluids was due to sodium. Forced removal of water from the body or, better still, deliberate reduction of water intake to a minimum led to a state of generalized dehydration in which both kinds of fluids suffered and to the same extent. The volume of both fell and the osmotic pressure of both rose. The fall in the volume of the extracellular fluids prevented the normal exchanges of metabolites between the blood and the tissues and reduced the functional capacity of the kidneys. This

state of generalized dehydration could be cured by the administration of water alone.

Forced removal of sodium from the body compelled the organism to compromise between reducing the volume of its extracellular fluids and allowing their osmotic pressure to fall. The fall in osmotic pressure further disorganized the kidney and in addition embarrassed the body cells by making them take up water in order to bring their osmotic pressure into line with that of the extracellular fluids. The only way in which the osmotic pressure of these fluids could be restored to normal and the comparative volumes of the cellular and extracellular fluids readjusted was by the administration of sodium salt and water. To give water alone was of no value. Saline must be given to all who had lost salt—that is to say, in all cases of diarrhoea and vomiting, heat-stroke, etc. It could be given by mouth or rectum or, most efficiently, intravenously. When the body was unable for any reason to excrete sodium salts their administration with water inevitably led to an increase in the volume of the extracellular fluids, and, if their administration was prolonged, to oedema. It was logical to restrict the sodium intake in these conditions, but relative salt deficiency might supervene insidiously, and if it did the treatment must be regarded as unsatisfactory.

The Potassium Level

Dr. R. S. AITKEN described a case of familial periodic paralysis in which reduction of potassium was a feature. The patient, a man of 21, had suffered typical attacks of paralysis of the arms and legs. The attacks occurred in the middle of the night and lasted for anything up to forty-eight hours. They occurred once every two or three weeks or oftener. A heavy meal shortly before bedtime was likely to bring on an attack, also the eating of a large quantity of sweets. The condition was thought to be connected with some disturbance of the electrolytes in the body, especially lactic acid, phosphorus, and potassium. It was found, however, that all the electrolytes before and after the attack were within normal limits, except potassium, which during the attack fell to about half its normal concentration in the serum—that is, about 9 mg. per 100 c.cm. instead of about 18. Potassium chloride given by the mouth was followed by the disappearance of the paralysis and the return of power to the limbs within about an hour. It was found that glucose induced an attack: also that insulin given at 11 p.m. brought about an attack at 4 a.m., which was cut short by the administration of 12 grammes of potassium chloride by the mouth. On glucose and insulin being given together the potassium in the serum descended precipitately and paralysis appeared and became complete so far as the arms and legs were concerned. Prostigmin had no effect on the paralysis, from which it might be concluded that the fault was not the same as in myasthenia gravis. The general conclusion was that in normal people sugar by the mouth, insulin by injection, sugar and insulin together, and adrenaline all produced moderate falls in the serum-potassium level. It was not known where the serum potassium went to out of the blood. In patients subject to periodic paralysis these agencies lowered the serum potassium to an unusual degree, and a flaccid paralysis came on, which with almost complete regularity was relieved within an hour by potassium chloride by the mouth. He was inclined to think that the lowering of the serum potassium was not the only condition necessary for the development of this peculiar form of paralysis.

Toxic Effects of Mineral Salts

Dr. C. L. COPE said that until recently mineral salts, although they had received attention from the pharmacologist, had been little regarded by the clinician. One important precaution to be observed in administering them was to have regard to the effect of the radical with

Analysis of Hospital Cases

Dr. Graham then gave an analysis of the cases admitted to his hospital (St. Bartholomew's) for diabetes during the period 1923-32 and their present condition so far as known:

Age Groups	Total Cases	Deaths	Unknown	Alive
0-5	2	1	-	1
5-15	29	6	8	15
16-25	46	15	5	26
26-35	44	17	6	21
36-45	52	19	7	26
46-55	59	22	7	30
56-65	45	23	4	18
65+	28	18	2	8
	305	121 (39.6%)	39	145 (47.5%)

These were cases which had been in hospital, and they were not quite a fair sample of diabetes cases, being too few at both extremes of age. The death rate in these cases had improved in the more recent years, due to the benefits of the high carbohydrate diet instituted in 1929. He had ascertained the cause of death in a number of these cases. It included coma in twenty-eight, pneumonia in twelve, bronchopneumonia in three, lung diseases in seventeen, influenza in seven, heart failure in eight, gangrene of legs in six, uraemia in four. He had been struck by the very poor resistance that these patients put up to pneumonia, but there was an improvement under the regime of adequate carbohydrate and fluid as well as insulin. One hundred unselected patients who came up to hospital in 1937 and had had diabetes more than five years previously had been examined, and the time since the disease began was from five to ten years in forty-six, eleven to fifteen years in thirty-nine, and sixteen years and over in fifteen.

Complications

On the subject of complications Dr. Graham said that the teaching that neuritis was common in diabetes did not tally with his experience, but one thing that did trouble these patients was very severe pain in the legs, described as "a shooting pain," exactly like the pains in tabes dorsalis. He had known a few patients who had the same pains very badly in the arms. The reflexes and sensations were preserved, and therefore it could not be that the nerve was implicated; it was probable that the pain was due to some central lesion. When the diabetes was got under control these patients lost their pains. In his list there were thirty-two ophthalmic patients, nearly all of them elderly people; sixteen had senile cataract. Patients sometimes came with perfectly normal vision, and on being given insulin they were unable to see, the eye becoming misty, but the condition cleared up later on.

One complication peculiar, so far as he knew, to his own clinic was that during the last three years about twenty-eight cases had developed jaundice, with very high van den Bergh reactions. With one exception they had all recovered, the exception being a man who developed a severe pyelonephritis. But they took a long time to get well, one of them eighty days. He had been very much disturbed by this occurrence. There was no common factor. He had a feeling that there was some infection which they picked up from one to another when they came to the out-patient department.

In conclusion he mentioned some of the disabilities under which diabetic persons laboured, even though their diabetes was controlled by insulin. They could not insure their lives, except at very high rates, nor could they take up any posts with pension rights, and they were gravely dis-

advantaged in regard to driving cars. He gave an account of the precautions on which he insisted if one of his patients was determined to drive a car. The trouble with these patients was that they might suddenly cease to recognize that their blood sugar was low, and then they went on and became unconscious or had an epileptiform convulsion. The perplexing thing about the condition was the way in which the symptoms suddenly changed. He instanced one man who suddenly developed a severe diuresis, also a very deep depression, and with depression some patients got violent headaches.

CROYDON TYPHOID REPORT

THE MINISTER'S VIEWS

Matters arising from the report of the inquiry into the outbreak of typhoid fever at Croydon¹ are reviewed in a letter addressed to the Croydon Corporation on February 21 by the Permanent Secretary of the Ministry of Health on behalf of the Minister, Sir Kingsley Wood. The letter is as follows:

SIR,—I am directed by the Minister of Health to inform you that he has considered Mr. Harold Murphy's report on the public inquiry held by him into the causes leading up to the outbreak of typhoid fever in the County Borough of Croydon in October and November, 1937. Sir Kingsley Wood, who has followed the course of the epidemic with the deepest concern, finds himself in agreement with the findings of the report, which he has no doubt have been also studied by the Corporation with the object of applying the lessons to be drawn therefrom for the guidance of their administration hereafter, and in particular as affecting the conduct of their water supply service.

The Minister is glad to observe that Mr. Murphy has been able to commend the skill and care with which cases of the disease were handled once they had been reported, and the efficient character of the hospital arrangements, the nursing, and the general medical services of the borough. On the other hand he cannot but feel that the Corporation will share his disquiet at Mr. Murphy's finding (as regards the water service) that the organization of the administration of the borough was such as to lead to "both misunderstanding and lack of communication between the responsible officers of the Corporation in connexion with the work." Sir Kingsley Wood trusts that the Corporation will at once review the whole field of their work in the light of this important consideration. A fundamental condition for the successful discharge of administrative responsibilities of the magnitude and complexity of those committed to the Corporation is the effective collaboration and co-operation of all the branches and departments into which the work must of necessity be divided. Mr. Murphy's report enforces the painful reflection that if this obvious truth had been sooner and more perfectly realized the calamity which we now have to deplore might have been averted. The Minister cannot too strongly impress on the Corporation the necessity for giving their immediate attention to this serious criticism, and he will be glad to be informed at an early date what steps they propose to take to remedy what experience has unhappily shown to be a grave defect in their administrative arrangements.

I am directed to request you to draw the attention of the Corporation to certain other points in the report which he considers to be specially important. The first is Mr. Murphy's finding that the borough engineer's duties covered so wide a range of matters as to make it impossible for him to give detailed personal attention to the highly important subject of water supply, and his consequential suggestion that the Croydon water supply should be under the direction of a fully qualified water engineer reporting to a water committee and keeping in close touch with the medical officer of health. The Minister commends this suggestion to the Corporation. In his view the water engineer should be a chief officer of the Corporation directly responsible to the water committee. He also considers it essential that the water committee and the water engineer should work in the closest co-operation with the Public Health Committee and the medical officer of health in all matters of common concern. He will be glad to be informed that the Corporation are making the necessary arrangements.

¹ The report was summarized at length in the *British Medical Journal* of February 19, 1938, p. 404.

the hearing showed improvement in all. They were tried with a salt-free diet, but the results were not so striking as with the water exchange. The salt-free diet seemed to accentuate the good effects of reducing the fluids, but with a salt-free diet an increase of fluids still caused bad symptoms. He had come to the provisional conclusion that the water was the important thing, although probably if one continued with the salt-free diet, and perhaps took other steps to eliminate sodium, that might result in improvement also.

The PRESIDENT (Dr. Tidy), in summing up, said that the right side of the heart must have an important part to play in the interchange of fluids. Any weakness of action there must come particularly into play when there were differences in the volume of the fluids in the body. Perhaps the plasma proteins and the part they took in this interchange had not been sufficiently considered. He wondered whether it was right to lump together, as Dr. McCance had done, the fluids in blood, lymph, and intercellular spaces as extracellular fluids. Surely there was a distinct difference between those fluids which were contained within the vessels and those which were outside. It seemed to him an artificial division, and he also wondered whether it was right to say that the osmotic pressures of the cellular and extracellular fluids were identical. It seemed to him a very big supposition, and against probability. He added that he had had two cases of aural vertigo, to which he gave a salt-free diet. The intake of water was not controlled. Neither of those cases benefited at all.

MEASLES: EPIDEMIOLOGY AND PROPHYLAXIS

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on February 25, Sir ARTHUR MACNALLY presiding, the subject of discussion was measles, to which Dr. J. A. H. Brincker, principal medical officer of the London County Council, contributed a historical, epidemiological, and aetiological study, and Dr. William Gunn an account of serum prophylaxis.

Dr. BRINCKER, in a short historical survey, said that the disease could not be recognized as such in any writings before Rhazes (tenth century). It was not until the sixteenth century that measles was accepted as an infectious disease. Even at that time there was still great confusion between measles and small-pox, and Thomas Phayre, in his *Book of Children* (1553), writing of "small pockes and meassils," said that "this disease . . . is of two kinds: varioli, ye meassils; and morbilli, called of us ye small pockes." Up to the eighteenth century the words "morbilli," "rubiola," "blacciae," "lenticula," "rossalia," and "rossania" were all mentioned in medical books, and there could hardly be any doubt that the present disease measles was referred to by those words. It might be assumed that in earlier times the exanthemata, at any rate measles and small-pox, were so common that they coexisted and often attacked the child at the same time. Sydenham gave a very clear description of measles epidemics in London in 1670 and 1674. In the first half of the latter year London was affected by a measles epidemic causing 795 deaths, and in the second half by one of small-pox causing 2,507 deaths. Sydenham hinted that many more deaths must have been indirectly due to measles, though they were registered under such headings as "convulsions," "diarrhoea," and "consumption."

Geography and Periodicity

Measles was met with in all countries and climates. It might be rarer in some than in others, but this was due not to latitude but rather to the accident of isolation from the densely populated communities where the disease was endemic. In London and in other cities both in this country and on the Continent it recurred in epidemic form at

regular intervals. The interval in London was two years. Usually this biennial epidemic began at the end of October, but its effect, as regards both incidence and mortality, did not become appreciable until the middle or end of the following January. Both then increased rapidly, to reach their maximum in April or early May, and then there was a rapid fall until the epidemic exhausted itself by the end of June. In temperate countries epidemics were more frequent in the colder than in the warmer months, but severe epidemics had been reported in the middle of summer in such countries as Spain and South Russia. Variability in the severity of outbreaks had been recorded in London and other English towns from time to time. In communities which had been long free from it measles might become widespread, severe, and associated with a variety of complications, and produce a very high mortality. There had been numerous epidemics where the mortality was for one cause or another excessively high—for example, in the Fiji Islands in 1875, when between one-fifth and one-quarter of the population died from measles or its consequences, and among the women and children in the Beer concentration camps in the South African War.

Turning to aetiology, Dr. Brincker said that the infecting agent or virus was known to be present in the blood of the sufferer during the period of invasion and perhaps up to the second day of the disappearance of the rash; thereafter it was irrecoverable from the blood and rapidly disappeared. Immunity due to the development of specific antigens rapidly took place in the body tissues, and these were present in the patient's blood soon after convalescence. Convalescent measles serum obtained from such a person might be used either to prevent an attack or to modify the disease in a person already infected with and incubating it. Infants at the breast had a high resistance to infection, possibly due to antigens derived from the mother. Children from 18 months to 2 years of age, on the other hand, were highly susceptible, and this susceptibility existed until about the fifth year, after which it diminished. These years of a child's life were also those during which it was susceptible to other diseases complicating measles, such as bronchopneumonia, and therefore the mortality at this age was significant. The question of prophylactic vaccination against the disease was still unsolved, but as success had already been obtained in such diseases as small-pox, distemper, and rabies, it was quite possible that this would before long be the case as regards measles.

Incidence and Mortality

So far as London was concerned, there had been a definite reduction in the death rate of measles since the eighties of the last century, and this became more pronounced during the first three decades of the twentieth century. Dr. Brincker showed the following table giving the death rate in London per million of population:

	Males	Females
1851-1860	573	493
1871-1880	558	463
1891-1900	631	539
1911-1920	417	308
1921-1930	192	146
1931-32	128	88
1933-34	120	96
1935-36	85	61

A big decline in mortality began in 1920 and had continued ever since. This drop in mortality was sometimes ascribed to the falling birth rate, but that could not be the case, for the number of cases of measles reported from the schools during every biennial epidemic remained the same. The diminution in the number of deaths must be ascribed to the general improvement in child health, also to the fact that both parents and teachers had come to recognize the disease as a serious one.

In spite of the fact that measles in this country was an endemic disease there were quite a number of isolated communities where it was non-existent, and when it was

which the salt was combined. One patient with some form of haemorrhagic disease was treated with large doses of calcium, and the physician attending him, knowing that the most readily absorbed salt of calcium was the chloride, administered that in considerable amount. Most of the calcium was excreted in the bowel, leaving, however, what was in effect hydrochloric acid in the body, resulting in a severe acidosis. If the lactose had been used all would have been well. The reason why such troubles did not occur more frequently was the efficiency of the normal organs of excretion, especially the kidney. The absorption of any salt tended to upset the ionic balance of the body fluids, and the kidney attempted to rectify the upset. When the excretory mechanism was impaired difficulty was likely to arise in mineral-salt therapy. For example, in pre-insulin and early insulin days much sodium bicarbonate was administered to the diabetic to combat acidosis, and cases of generalized oedema appeared to have been more frequent among diabetics then than they were now. The inference was that the oedema was due to the giving of too much sodium. Potassium also had its toxic action. Potassium citrate was given to nephritic patients to render the urine alkaline. If in such patients there was severe renal functional damage, then the urine would not so readily be made alkaline, and in those circumstances there was a temptation to increase the dose of potassium citrate, rendering the conditions very suitable for the development of potassium poisoning. The use of either potassium or sodium citrate in renal damage was liable to lead to another ill result. An excess of the alkaline ion was liable to be left behind in the body, with the result that alkalosis was produced, and if the kidney was damaged the alkalosis might remain unrelieved.

Another supposedly innocuous substance was magnesium, which was given in large amounts as the sulphate for its effects as a purgative. When a full magnesium dose was given to a person with healthy kidneys some went into the blood stream and was excreted rapidly, but when renal function was damaged it was a different story. The normal level of the magnesium in the plasma was very constant at about 2 mg. per 100 c.cm. of blood. But if in a severe nephritis the full purgative dose of magnesium sulphate were given the plasma magnesium might rise considerably, even to 10 or 15 mg. per cent. He wondered how often coma had been precipitated by a well-meant dose of Epsom salts. An important feature of the clinical condition in such cases was depression, mental lassitude, irritability, and drowsiness, precisely the symptoms to be expected in mild magnesium poisoning. Vast amounts of stomach powders were taken by sufferers from various types of indigestion, in many cases not under medical supervision, and these patients remained in a state of depression due to the continuous ingestion of magnesium. Referring to calcium, Dr. Cope said that in the majority of individuals this was satisfactorily dealt with, and in a series of patients with gastric ulcer under treatment with alkalis containing calcium carbonate there was no sign of retention. But when alkali poisoning did develop in such individuals the calcium in the blood was greatly increased. He had found such values as 16 to 18 mg. per cent. instead of the normal 10. He was not prepared to say that such high blood-calcium levels did definite harm, but a certain proportion of persons taking powders for stomach complaints did suffer from high blood calcium, and the possibility that the prolonged taking of large amounts of calcium might in time have a serious effect on the kidney was at least worthy of consideration.

Excess Iron and Rickets Causation

Dr. J. F. BROCK said that it was now possible to state definitely that one mineral when present in excess in the diet could interfere with the absorption of another mineral and cause deficiency. The simplest way to produce ex-

perimental rickets in rats was by the Steenbock diet, in which the amount of calcium was much increased in relation to the amount of phosphorus. Some years ago he was impressed with the possibility that large doses of iron might have a similar effect, and he discovered that diets containing a considerable excess of iron could produce in rats exactly the same type of rickets. The reason for this was that the excess of iron present in the gastrointestinal tract precipitated phosphorus in the form of insoluble phosphate and gave the rat a phosphorus deficiency. Rickets could be produced not only with an excess of ferric chloride but with any iron preparation, and it had been recorded in various countries that the same sort of rickets resulted when other minerals—magnesium, beryllium, strontium, and aluminium—were added in excess to diet. Applying these principles to man, he had attempted to find out whether the ordinary large therapeutic doses of iron that were used to-day might have any effect on the human phosphorus metabolism. He found that consistently the addition of large quantities of iron caused an excess of phosphorus excreted in the stools. But with the ordinary conditions of diet, notwithstanding the high iron dosage, there was also such an excess of phosphorus as to cause no danger of deficiency at all. In one patient, however, who was on a very low phosphorus diet, the stool phosphorus was raised by the addition of large quantities of iron, and the effect was to bring about a negative phosphorus balance. He was not suggesting that any person had been given rickets as the result of the therapeutic administration of iron. The amount of iron given therapeutically would never cause anything beyond a transient deficiency in the phosphorus. But if the ratio of Fe to P were raised over a certain critical level a deficiency was caused.

Sir WALTER LANGDON-BROWN referred to some French observations to the effect that myasthenia gravis was caused by an adenoma in the thymus, in the same way that hyperparathyroidism caused von Recklinghausen's disease. The biochemical effect of this adenoma was that it raised the sodium content and lowered the potassium, so that good could be done by giving potassium salts and harm by giving sodium—just the reverse of the conditions obtaining in Addison's disease. He thought that the danger of taking alkaline powders in large quantities was one which should be recognized. Dr. E. N. ALLOIT said that, where there was dehydration to begin with, hypertonic saline was a very dangerous drug. It had its advantages, but it should be used with great caution. He also stated that he had had the opportunity at Cambridge of investigating two further cases of familial periodic paralysis of the kind that Dr. Aitken had brought forward. It could be said quite definitely that the potassium in these cases did not go out in the urine; it was retained in the body. The present interpretation of the facts was that for some unknown reason there was an abnormal demand on the potassium in these affected subjects, and that the fall in serum potassium was a reflection of that. Some neuromuscular abnormality as well as some abnormality in dealing with potassium must be postulated.

Salt and Fluids in Treatment of Aural Vertigo

Mr. TERENCE CAWTHORNE referred to cases of aural vertigo. It had been stated that in these cases the attacks of vertigo diminished on the reduction of the water and the salt intake, and that the hearing was very much improved. More recently it had been affirmed that with a sodium-free diet these patients could take unlimited water and did not get vertigo. He had tested the matter out in seven typical cases. The fluid intake was increased, but the vertigo, tinnitus, and deafness were made much worse. The fluids were then cut down to 20 oz. a day in four cases, and in the three others, which could not tolerate that low level, to 30 oz. In six out of the seven cases the vertigo disappeared; the tinnitus went in five, and in a sixth was very much better, and the measure of

MASCULINE FEMALE Pelves

A meeting of the North of England Obstetrical and Gynaecological Society was held in Manchester on January 28, at which Dr. JOHN CHISHOLM took the chair in place of the retiring president, Dr. J. W. BRIDE.

Mr. PERCY MALPAS (Liverpool) read a paper on the masculine pelvis in women. He said that Caldwell and Molloy considered that the main characters of the "android" pelvis were a forward displacement of the sacrum, causing shortening of the posterior segment of the inlet; relative straightness of the ilio-pectineal lines, which pass backwards from the pubes at an acute angle, giving rise to a narrow fore-pelvis; and a tendency for the sacrum to be vertical. Thoms, in 1933, described a series of cases in which transverse narrowing of the inlet was found in association with occipito-posterior positions, and he considered that many of these pelves belonged to the male type of the inverted pelvis of Berry Hart. Hart's papers represented the most important contribution to the subject of the masculine pelvis. He thought that either the ilio-sacral or the ischiopubic segments of the female pelvis might undergo inversion into the male type. An important aspect of Hart's cases was that the patients exhibiting pelvic inversion also showed other evidence of pseudo-hermaphroditism. The characters of the masculine pelvis in women were still far from decided. Many of the anatomists' criteria were not applicable in obstetrical practice, and the relationship between the assimilation pelvis and the masculine pelvis still required elucidation. Three recent cases had called his attention to the problem.

CASE REPORTS

The first patient, a primigravida, was admitted for a persistent occipito-posterior position, which necessitated a forceps rotation. Extraction was difficult on account of antero-posterior as well as transverse contraction of the bony outlet. The iliac bones were small with the rough incurved crests seen in the male pelvis; the sacral promontory could not be reached. Lateral radiographs showed an extension of the sacral articular surface on to the third sacral vertebra, a long six-piece sacrum due to low assimilation, and a false promontory between the first and second sacral vertebrae. The patient was tall and heavily built, with pronounced hirsutes and a general male distribution of body hair.

The second patient had a persistent occipito-posterior position in her first labour, which lasted eighty-one hours and ended in a stillbirth. Her second labour was normal. She had the heavy, incurved, small iliac crests characteristic of the male pelvis. X-ray pelvimetry showed all the measurements of the brim to be the same, the sacral curvature was increased, there was low assimilation, and the angle of inclination of the brim was greater than normal. The patient had hirsutes, which she concealed by shaving, and a general male distribution of hair.

The third patient, as yet undelivered, also exhibited hirsutes and a male type of hair distribution. The iliac crests were of the male type. Radiographs revealed the brim of the pelvis as circular, the sacrum showed low assimilation, was articulating with the ilium by two and a half pieces, and had a well-marked false promontory. The angle of inclination of the brim was raised.

Mr. Malpas considered that evidences of sex intermingling other than those in the pelvis should be taken as a criterion in the selection of cases from which the features of the masculine pelvis were to be worked out. The main characteristics appeared to be a vertical or forward-curving sacrum, low assimilation making a six-piece sacrum, an increased angle of inclination of the brim, and a well-marked false promontory. While contraction of the outlet was probably of importance, its measurement was more difficult than was generally supposed; antero-posterior bony contraction had not

received as much attention as it deserved when compared with transverse contraction. Pelves of the masculine type were undoubtedly responsible for some cases of persistent occipito-posterior position.

At the same meeting Mr. F. J. BURKE (Liverpool) described a granulosa-celled tumour of the ovary occurring in a woman aged 54; Dr. E. A. GERRARD (Manchester) discussed two cases of large tumours complicating pregnancies, one a large parovarian cyst and the other a large pedunculated subserous fibroid; Dr. W. W. WRIGHT (Stoke-on-Trent) read notes on a case of locked twins associated with toxic albuminuria and profound intrapartum collapse; and Professor DANIEL DOUGAL recorded a case of incomplete cervical abortion. In the discussion which followed Professor A. H. CLAYE, Professor MILES PHILLIPS, Miss RUTH NICHOLSON, and Mr. F. H. EDWARDS took part.

DIABETIC OUT-PATIENTS

The management of diabetic out-patients was discussed at a meeting of the London and Home Counties Branch of the Medical Superintendents' Society on January 20.

In opening Dr. H. P. HIMSWORTH quoted certain American statistics and a prophecy that diabetes is likely to be as prevalent as pulmonary tuberculosis within a few years. In 1936 the deaths in this country from diabetes were as numerous as those from all the infectious diseases together. The number of patients attending his own clinic at University College Hospital was increasing by 200 every year; the total admissions last year were sixty-five, out of 900 attending. One hundred more patients were scattered about in other departments of the hospital, and perhaps half of these were admitted. An efficient clinic was essential, and having one man in charge secured continuity of treatment and helped to gain the confidence of patients.

Organization of a Diabetic Clinic

Four important requirements of a diabetic clinic he discussed briefly. First, a dietitian, who should be able to explain a dietary to the patient in simple language, paying due regard to his or her economic position. Secondly, a technician was needed for analysis of urine. Dr. Himsworth did not approve of casual blood-sugar estimations; glucose-tolerance curves were essential in many cases for diagnosis. He placed great reliance on the ferric chloride test for acetone bodies. The nitro-prusside test, positive at about 1 in 400,000, was very sensitive, but a positive ferric chloride reaction, given at a concentration of about 1 in 1,500, provided a most useful warning of imminent coma and was an indication for immediate admission. Thirdly, the services of a chiropodist should be obtained; in his two years' personal experience of such an arrangement the incidence of gangrene had been halved. Lastly, the chest should be x-rayed at the patient's first attendance, and annually thereafter. The rate of incidence of pulmonary tuberculosis was 6.5 per cent, and the condition was most common in the 45 to 50 age group. Prognosis was at least as good as in non-diabetics if the diabetes was controlled and the pulmonary disease diagnosed early. Clinics could be relatively centralized and could deal with about 100 patients in one session, about six being new cases. The co-operation of the district nursing association was of great importance.

On admission, if the ferric chloride test was positive and if the patient could swallow, 50 grammes were given by the mouth and 25 units of insulin were injected every three hours till the urine was free from acetone bodies. Diets were weighed daily at first, later weekly. Actual menus were provided by the dietitian, about half a dozen alternatives being possible for each meal. Treatment was by diet alone for the first week if there was not much

accidentally introduced it behaved like a new disease and affected the susceptibles in that closed community until they were exhausted. At the other extreme, in an urban community like London, where the disease recurred as regularly as clockwork every two years, one could almost predict the very week in October when the disease became epidemic and began to spread from district to district and school to school. In New York the periodicity curve of measles appeared to be undergoing a state of evolution similar to that experienced in London in 1912-18. Two successive years of epidemicity were followed by one of non-epidemicity, and these by an epidemic year followed by a non-epidemic one, and then the curve repeated itself by a succession of two epidemic years followed by one of non-epidemicity. What was responsible for this "break-step" phenomenon as well as the persistent lower mortality of measles in New York when compared with that in London could not as yet be explained. Dr. Brincker showed a table giving the figures for New York since 1910, with the comparative figures for London. The figures for the last eight years were as follows:

Year	New York		London	
	Deaths	Death Rate per 1,000	Deaths	Death Rate per 1,000
1930	154	0.02	1,027	0.23
1931	134	0.02	115	0.03
1932	58	0.01	822	0.19
1933	213	0.03	101	0.02
1934	25	0.00	855	0.20
1935	105	0.01	19	0.00
1936	81	0.01	564	0.14
1937	25	0.00	25	0.01

Serum Prophylaxis

Dr. W. GUNN, medical superintendent of the North-Western Fever Hospital, said that at present in this country only the fever hospitals held stocks of convalescent serum, which was usually available in small amounts to public health authorities and to private practitioners. Much larger stocks of adult measles or normal serum were maintained by general and fever hospitals and by certain public health authorities. At least two commercial firms which specialized in the manufacture of biological products made, or were prepared to make, immune measles serum from blood collected under proper conditions by private practitioners or public health authorities. Placental extracts had been prepared by the Lister Institute and by the L.C.C. serum laboratories, Belmont. He touched on difficulties not yet solved—namely, the estimation of serum potency, the determination of the fact of invasion following exposure, and the problem of human controls, including the disturbing factors of chance and latent immunization by subclinical attack.

After showing some tables, Dr. Gunn said that it would be deduced that those concerned were rather disappointed in their results, which seemed to get worse with each epidemic, instead of better. The probable explanation was twofold. It related first to the selection of donors. When the work started this selection was most carefully done, but with an increasing number of workers the same care was not always exercised, and sometimes cases of rubella in adults crept in. The second reason was that not enough care was taken in the recording of the data, so that as the scope and range of the investigations extended the reliability of the results diminished. He was afraid that the scope of the method would not be greatly improved until, first, the serum was readily available at all times when required, and, secondly, deliberate exposure was practised whenever circumstances called for

it. Whether legal consent to the practice of prevention and attenuation of measles by serum was necessary in hospital work was a matter of opinion. The consent of the parents or of those *in loco parentis* should always be obtained if possible, but if this would result in undue delay one should proceed without it. The legal aspect of inoculating children without consent had not yet, so far as he knew, come before the courts, but it might well come about that failure to use the method would at some time or other be accounted negligence, and therefore one was between the devil and the deep sea.

Discussion

Sir ARTHUR MACNALT said that Dr. Gunn had alluded to an early report of his which he worked on more than twenty years ago, when they were all very much concerned to reduce the mortality of measles. The main recommendations made at that time were to impress upon parents the seriousness of measles as a disease, to endeavour as far as possible to prevent the child contracting the disease before the age of 5 years, to ensure precautions being taken in the home against the complications, especially respiratory, of measles, and to emphasize the grave after-effects through lack of attention to the eyes and ears. These instructions from the Local Government Board did gain a wide circulation through the efforts of school nurses and health visitors, and the position had been greatly improved by the measures for infant and child welfare. It was to be hoped that the further researches, such as Dr. Gunn had carried out, would reduce the mortality to a still greater extent.

Dr. J. E. MCCARTNEY said that the donors of serum at L.C.C. institutions were healthy adults. So far as was known no untoward result had followed the administration of the serum. Well over 100 litres had been used. Had any form of virus infection taken place the fact would have been notified. Dr. W. A. DALEY asked whether the progressive reduction in the death rate from measles was due to the fact that the virus had changed in its potency. Was measles like small-pox in the respect that there were viruses of different character or strength? Was the improvement due to the increased resistance of the individual to attack or to the efforts made to impress parents that complications should be prevented? Further, did chill in itself precipitate an attack of bronchopneumonia, and what was it that caused some children to develop bronchopneumonia while others escaped? Measles had been known for many hundreds of years, but yet he felt that the knowledge of the subject was still somewhat patchy. Dr. R. A. O'BRIEN referred to the difficulty of ensuring a supply of serum. There was a wave of measles all over the country at present, and there were agitated demands for the serum which was not available. Convalescent serum was difficult to get, and there was no central organization for obtaining adult serum. Dr. RICHARD HAMBURGER said that bronchopneumonia was the principal danger for the younger child, and the high incidence of this condition might perhaps be explained by the fact that these children were always lying on their back during their illness, and thus a hypostatic state was favoured.

Dr. S. MONCKTON COPEMAN, as a member of the London County Council, spoke of the administrative problems which the biennial epidemic of measles, now at its height, imposed. He also said that an endeavour was being made to bring into force the general notification of measles in London. It had been suggested by opponents of compulsory notification that it would mean more cases coming under the care of the authorities, and therefore the difficulties of hospital accommodation and nursing would be increased. But it might, he thought, have the opposite effect, because if, as a result of notification, cases could be dealt with in the extremely early stages, extension in the home or school might be prevented and thus the total numbers would be lessened.

more fatal than any other single disease except cancer. It was necessary to impress on everyone the importance of seeking treatment as soon as there was reason to fear infection and of learning how to prevent the spread of infection. Venereal diseases were another scourge on which a special attack was being made at this stage of the health campaign. These diseases were particularly insidious in their effects. There was no sphere in which the perils of ignorance and neglect were more terrible or the spread of knowledge more necessary. It was essential that all cases should be promptly discovered and treated, and that the patient who was under treatment should persevere until his system was certainly free from the poison. The family doctor was still the first line of defence against ill-health, and his co-operation in helping to expand the health services was invaluable, just as the health services could also help the doctor—for example, the tuberculosis service. Co-operation was, perhaps, the most important requirement of all in the improvement of health and happiness.

Epsom College

The Council of Epsom College will shortly proceed to elect one or more St. Anne's scholars. Candidates must be fully nine years of age, and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of the scholarships is dependent on the means of the applicants, the locality and fees of the schools selected. Application must be made by May 1, 1938, on a form to be obtained from the Secretary of the College, 49, Bedford Square, London, W.C.1.

Appropriation of London Public Health Institutions

Six public health institutions under the administration of the London County Council remain to be appropriated for the reception of the sick. These are the Fulham, St. Mary Abbots, Hackney, St. Leonard's, St. Allege's, and St. Pancras institutions. There are still some able-bodied healthy and infirm inmates in these institutions in addition to sick patients, but during the next few weeks all the former will be transferred to public assistance establishments, and by April 1 the appropriation of the six institutions will be effected. Each of them adjoins and is within the curtilage of a hospital of the same name. With the appropriation of these six institutions the Council has completed its task, first entered upon in 1929, of removing as soon as circumstances permitted its hospital service from the ambit of the Poor Law. After appropriation the whole of the available accommodation will be utilized for sick patients. Certain medical staffing arrangements are proposed, to be reviewed at the end of two years. The medical superintendents of the hospitals to which the institutions are attached have in five cases had an additional allowance as medical and administrative heads of the institutions, and this is now to be incorporated in the basic salary in four of the cases and to be subject to the usual increment. In the fifth case, that of Hackney Hospital, the scale of salary of the medical superintendent is £1,200-£50-£1,450, and an additional allowance of £50 a year has been received in respect of the institution. On appropriation the combined institution will provide accommodation for a large number of sick patients, approximating to that of Lambeth Hospital (£1,250), and the scale of salary is to be the same as for Lambeth Hospital—namely, £1,400-£50-£1,650. In three of the institutions the position ranking next to that of the medical superintendent is to be upgraded.

It was announced in the *American Heart Journal* for December, 1937, that this was the last issue to appear under the editorship of Dr. Lewis A. Conner, under whom the journal has arrived at its present high position. He has been succeeded by Dr. Fred M. Smith, Professor of Medicine in the State University of Iowa.

Correspondence

Raw or Pasteurized Milk

SIR.—The important question, Should raw or pasteurized milk be given to children? is much to the fore at the present time, and although the medical profession generally is strongly in favour of pasteurized milk, governmental action has long been delayed. It is true that the Board of Education has repeatedly urged that efficiently pasteurized milk, where such is available, should be supplied in schools; and that the Government has announced its intention of introducing legislation which will enable local authorities, if they so wish, to secure that all but tuberculin-tested milk is pasteurized in their areas. This is a minimum measure, and it is to be hoped, therefore, that the Government's proposals will be in no way weakened during their passage through Parliament.

Any lingering doubts should be removed by the report from the *Journal of Dairy Research* for October, 1937, by Wilkie, Edwards, Fowler, and Wright on the relative value of raw and pasteurized milk in the feeding of calves, from which I quote the following from the "summary and conclusions":

1. Bull calves from tuberculin-tested Ayrshire herds were fed on raw or commercially pasteurized milk up to 12 weeks of age, in amounts strictly in relation to their body weight. This diet was supplemented from the eighth week by hay at the rate of 2.3 lb. per head per day. The milk used was mixed milk from untested herds, the raw and pasteurized milk being derived from the same bulk sample.

3. No appreciable differences were noted in the skeletal growth of the two groups. Marks awarded by experienced stock judges showed consistent differences in favour of the pasteurized-milk-fed group, although the significance of such differences cannot be assessed.

4. Inoculations of grouped daily aliquots of raw milk twice weekly into duplicate guinea-pigs resulted in finding viable tubercle bacilli in 70 per cent. of the samples, and *Br. abortus* in 38 per cent. of them. The pasteurized milk samples were uniformly negative to both tests.

The differences in tuberculous infection of the two types of milk were reflected in the results of tuberculin tests and post-mortem examinations on the calves at the conclusion of the experiment. Twenty-four out of thirty-six calves fed on raw milk reacted to the test, and the presence of tuberculous lesions was confirmed in twenty-three by post-mortem examination. One calf in the pasteurized-milk-fed group reacted to the test, but exhaustive post-mortem examination and inoculation of glandular material into guinea-pigs failed to confirm the presence of any tuberculosis.

5. This work has failed to show any significant differences in the nutritive value of raw and of pasteurized milk for the rearing of young calves. The use of pasteurized milk, however, had a clear advantage in that it preserved the animals from infection through drinking milk containing living tubercle bacilli.

Again, in the report on tuberculous disease in children by John W. S. Blacklock (issued by the Medical Research Council in 1932) we find it stated:

"Of twenty-eight cases of tuberculous cervical adenitis, ten were infected with the human type of bacillus and eighteen (64.3 per cent.) with the bovine. . . . In twenty-six cases of tuberculosis of bones and joints, seventeen were due to infection with human strains and nine (34.6 per cent.) with bovine, the incidence of the latter being practically the same in town and country."

It will be remembered that within the last two years the Royal College of Physicians reported its unanimous opinion in favour of all milk sold in Great Britain being

acetonuria. Insulin was given if acetone was present in the specimens of urine taken before and after breakfast.

Factors in Prognosis

Dr. B. A. YOUNG emphasized the importance of estimating the prognosis of a diabetic in relation to (1) his financial position, (2) his intelligence, and (3) the skill of his medical attendant. The increase in the number of diabetics over the age of 50 was due to the ageing of the population in general, and to the increased duration of life of diabetics. He referred to the difficulty under some authorities of securing any reasonable degree of continuity of treatment. He mentioned the general practitioner's appreciation of information relating to the dosage of insulin, the dietary, etc. He advocated periodic lectures for district nurses, and stressed the importance in poor localities of high carbohydrate diets, owing to their cheapness as compared with high fat or protein diets.

Dr. Young exhibited models used by him to illustrate portions of different foodstuffs, which he had found of value in the treatment of the less intelligent diabetic. Definite schemes for large municipal authorities were advocated with clinics centralized to promote continuity and standardization of diabetic treatment.

distant countries. It had grown in size and in efficiency, and while the annual cost in 1914 had been £60,000, in 1937 it was £180,000. The new extensions would mean still greater cost.

Glasgow Rheumatic Clinic

Speaking at the annual meeting of the Glasgow Orthopaedic and Rheumatic Clinic on February 24 Sir Hector Heisterington, Principal of the University, said that the morbid conditions with which this institution was concerned were receiving more and more attention from the public, the medical profession, and medical science. It was certain that there were few cities and districts which had a greater need of this service than Glasgow and the western district of Scotland. By reason of the climate and of the nature of the main industries, illness and accident in that area called for treatment by the methods offered in the institution. They were discovering to-day that a higher standard of physical well-being was possible, and that to remedy conditions which did not seem at first sight to be very serious added greatly to human efficiency and happiness. The report of the institution showed that 3,044 patients had been treated during the year, involving 104,700 separate treatments. The expenditure had been £6,300, to which the patients themselves had contributed about £5,000.

SCOTLAND

Edinburgh Medical Officer of Health

The Public Health Committee of Edinburgh has unanimously recommended the appointment of Dr. William George Clark, at present deputy medical officer of health for Edinburgh, to succeed Dr. John Guy, who is due to retire from the post of medical officer of health for Edinburgh in October. Dr. Clark graduated M.B., Ch.B. at Glasgow in 1910 and took the D.P.H. of Cambridge in 1920. After holding posts as house-physician and house-surgeon in Glasgow Royal Infirmary and assistant medical officer in the Belvedere Hospital, Glasgow, and Brook Hospital, London, Dr. Clark became assistant medical officer in Woolwich Tuberculosis Dispensary and was later appointed assistant medical officer of health in Glasgow. From this post he was appointed deputy medical officer of health for Edinburgh in August, 1935. It was agreed by the Public Health Committee that the salary should be at the rate of £1,500 per annum rising by five annual increments of £50 to £1,750. It was also resolved that the medical officer of health might, with the consent of the committee, accept any appointment as professor or lecturer in connexion with the instruction of students, provided this did not interfere with the discharge of his primary duties.

Edinburgh Royal Medical Society

The annual dinner of the Royal Medical Society of Edinburgh, now in its 201st year, was held on February 24. Dr. G. J. Cleland, senior president of the society, presiding. Mr. W. J. Stuart, in proposing the toast of "The Royal Medical Society," reviewed the changes that had taken place in clinical teaching during the past forty years. He felt that at the present time students did not get enough to do in the wards. Mr. John R. Little, chairman of the managers of the Royal Infirmary, replying to the toast of "The Royal Infirmary," said that its principal difficulties at the present moment were financial, although they also greatly lacked adequate publicity. The Infirmary was not a parochial but a national institution, receiving patients from all over Britain and indeed from

ENGLAND AND WALES

Rheumatism Research in Leeds

The third annual report of the Leeds Advisory Committee on Research into Rheumatism has now been issued; it relates to the year 1937. Dr. D. H. Collins, the committee's research fellow, states that work is continuing on the reactions of the peripheral circulation in rheumatism to temperature influences. He mentions the great advantage conferred by the direct association of abundant specialized clinical material with the resources of the scientific departments of a university medical school. New apparatus and further technical assistance have been obtained for the histological study of rheumatic bones and joints, and the accumulated data from clinical and radiological examinations are expected to contribute to the fundamental pathological knowledge, which has been so scanty hitherto as regards rheumatism. Eight papers have been published during the last three years. A second research fellow, Dr. W. Goldie, was appointed last March, and a follow-up investigation was undertaken of cases of arthritis treated by gold injections at the Leeds Public Dispensary and Hospital. Research is now being conducted on the incidence of antibodies in the blood of patients with rheumatoid arthritis to the *Streptococcus haemolyticus* and other bacteria; the influence of gastric acidity on the incidence of toxic reactions in cases treated by gold; the excretion of gold in man; the blood changes produced by gold injections; and the investigation of a patch test for hypersensitivity to gold salts. An attempt is also being made to reproduce rheumatic lesions experimentally in animals by dietetic and infective means. Lord Harewood, chairman of the Advisory Committee, believes that the work of the committee is capable of considerable development in association with the Empire Rheumatism Research Council.

Co-operation in Health Services

Dr. Thomas Carnwath of the Ministry of Health, when opening the King's Lynn Health Week, paid a tribute to the work of the Central Council for Health Education in helping to organize the activities of the week. The last half-century, he said, had seen tuberculosis pass from being "normally incurable" to "normally curable," but only if treatment was begun in time. The standardized death rate from tuberculosis had declined from 2,453 per million in 1885 to 657 in 1937. It was still, however,

under my care to the Princess Elizabeth of York Hospital for Children have all been treated with eumydrine and with uniformly successful result, the vomiting in no case having persisted longer than ten days after its inception. While not in any way wishing to detract from the success which follows surgical intervention, as revealed in Mr. Levi's series, I should be astonished if such excellent results are the experience of the average paediatrician with surgical measures. At any rate, when I review all the examples I have had submitted to operation, the mortality rate is much higher than the 2 per cent. obtained by Mr. Levi. And I might further add that I have compared the results of surgical and medical treatment in cases from the same class of material (as, for example, hospital or private), and find that there is no difference in the recovery rate.

If I personally had any criticism to make of Dr. Braithwaite's communication it would be regarding the basis on which he made his diagnosis. From the evidence supplied by Dr. Braithwaite I should be doubtful if all his patients were in reality suffering from hypertrophic pyloric stenosis. Dr. Braithwaite did not depend, as I think most paediatricians would, on the presence of a palpable tumour, but he took as the pathognomonic feature the radiological findings, which of all the signs of the disease are the most fallacious. Anyone who takes the trouble to submit a series of infants with and without hypertrophic pyloric stenosis to a radiological investigation will discover that there is such variation in the motility of the stomach in both of these conditions, and that no help in diagnosis is possible in this way. It is no doubt for this reason that there is such a want of unanimity among radiologists regarding the particular radiographic features which are diagnostic of hypertrophic pyloric stenosis.—I am, etc.,

London, W.1, Feb. 28.

LEONARD FINDLAY.

Excision of the Patella

SIR.—I read with interest in the *Journal* of February 19 two articles on "fractured patella." Mr. G. O. Tippet supports Mr. Brooke in excision, but gives us as a fourth indication "congenitally displacing patella," which Mr. H. Jackson Burrows condemns urgently, and with this condemnation I certainly concur. My experience of Brooke's operation is limited to three cases, but I give them to support his theory.

Twelve years ago a youth of 18 was admitted to one of my beds with a compound comminuted fracture of the left patella, and septic arthritis of the knee-joint had already supervened. Immediate operation, with total excision of contaminated tissues and all patellar fragments and drainage of the joint, led, to my delight, to full function of the joint in four to five weeks.

In April, 1937, a young man of 26 came under my care with a patella refractured within six months of a fibrous union in poor position. I excised his patella and he did equally well.

A month later I was called to a hospital in the district to treat a fractured patella in an old man of 83 with a grossly comminuted patella, which I removed *in toto*. This week, while consulting his doctor on a family surgical emergency, I heard that he now mounts the same ladder in his draper's shop to deliver the hosiery as before.

This, I am sure, speaks well for Brooke's operation, so ably supported by Professor Hey Groves, and I venture to predict it is the operation of the future in selected cases.

I trust that the operation of wiring of the patella is now an anachronism, and that routine cases should be treated by catgut apposition.—I am, etc.,

Oxford, Feb. 19.

HUGH WHITELOCKE.

SIR.—Mr. G. O. Tippet ends his article on this subject (*Journal*, February 19, p. 383) with the words: "Lastly, we must note Brooke's claim that the power of extension of the knee is better without a patella than with one." If this be so I foresee the likelihood of stretching the crucial ligaments with consequent instability of the knee-joint. The possibility of such an undesirable end-result might well be kept in mind by those contemplating the routine adoption of this seemingly rather drastic measure.—I am, etc.,

Onchan, Isle of Man, Feb. 24.

P. W. HAMPTON.

Contraceptives and Fertility

SIR.—As a member of the medical subcommittee of the National Birth Control Association I should like, if I may, to reply to the letters from Mr. V. B. Green-Armytage and Mr. G. H. Alabaster in the *Journal* of February 19 (p. 419). There seems to be some misconception in their minds as to the point which we were attempting to make. Surely everyone who has dealt with cases of sterility—and many such cases come to the birth control clinics—is in agreement with Mr. Green-Armytage and Mr. Alabaster when they stress the importance of cervicitis and abnormal cervical secretions as factors in the production of infertility. We did not wish to raise the moral, social, and obstetrical issues involved in the deliberate postponement of pregnancy, for again we are probably in agreement with your correspondents that there is much to be said on all these counts in favour of early child-bearing. The mere postponement of the first pregnancy, by whatever means, is in itself conducive to sterility, since fertility in the female decreases rapidly with age. The point which we do not consider proven and about which we wish to join issue with Mr. Green-Armytage is his contention that the use of certain contraceptives (caps and acid chemicals) before the first pregnancy increases the incidence of cervicitis. His suggestion that infection of the cervical canal commonly follows the use of a cap is a grave one and has far-reaching implications, yet it is unconvincing. Might not the bacteria introduced during normal coitus be equally culpable? Those of us who draw our patients from rural areas, where the use of chemical and mechanical contraceptives in early married life is still extremely rare, can quote many cases of nulliparous women who are found on examination to have cervical erosions and other evidence of cervicitis. With regard to his point about the upsetting of the physiological pH of the vagina, there does not at present appear to be any satisfactory evidence that the introduction of acid substances into the vagina has more than a transient effect, owing to the excellent buffering action of the vaginal and cervical fluids, nor is there evidence that the mere lowering of the vaginal pH *per se*, excepting by solutions more strongly acid than those used in contraception, can cause erosion of the cervix and cervicitis. These points are actually being investigated by the committee.

If the things of which Mr. Green-Armytage complains are liable to induce cervical infection and subsequent sterility in nulliparae, then why will they not do so equally in multiparae whose cervixes are already more or less damaged? Yet all the evidence accumulated at the birth control clinics, from thousands of cases, indicates that

pasteurized, and suggested that even Certified and Grade A milk should be similarly treated as a counsel of perfection in the interests of the public.

We have all seen cases similar to the following.

A few years ago a lady consulted a paediatrician about her child, who was going for a holiday on a farm. He told her that it was necessary for the child's milk to be obtained from the mixed milk of at least three cows, and essential that it be boiled before use. The reasons were explained to the mother. Upon arrival at the farm the mother saw a cow which she described as having a kind and pathetic face, and arranged for the milk from this cow alone to be given to her child. Unfortunately it was given raw, after all the injunctions to the contrary. Within four months the child was dying of generalized tuberculosis, although previously there had been no indications of this disease. The cow was killed and found to be riddled with tuberculosis.

The evidence in favour of all milk being pasteurized is overwhelming, and I have no doubt that at no distant date the sale of any milk other than pasteurized will be looked upon as a criminal offence, as it is a safe milk and its nutritive value is fully equal to raw milk.

It is the duty of every authority or other body responsible for the health of the people living within its area to consult the medical officer of health attached as to what procedure is essential, and I have no doubt that the medical officers of health, who have all the knowledge and experience necessary to form an unbiased judgment, would give a very decided lead in favour of universal pasteurization of milk. With tuberculosis so rife it is important that strong action should be taken immediately by all those responsible (including Government action) for the supply of pure and safe milk to the inhabitants of Great Britain. Hesitation should be unthinkable.—I am, etc.,

BERNARD MYERS.

Insulin-tannic-acid-zinc Suspension

SIR,—The observations of Drs. C. N. Jenkinson and K. J. G. Milne on the above new compound published in the *Journal* of February 19 (p. 380) call for a few remarks. They conclude (1) that the compound is unpleasantly painful to most patients, but (2) that otherwise it shows retarding qualities similar to those of zinc-protamine-insulin, and "can effectively replace zinc-protamine-insulin in the treatment of diabetic patients." With the first conclusion I am in painful agreement, as I injected an experimental tannic-acid-insulin preparation into myself about a year ago to my intense discomfort. With the second claim I cannot agree after a careful study of the details of the nine cases in Table I, which hardly support their conclusion but in my opinion contradict it. For instance, in Cases 1 and 2 no fasting blood sugars are given to show the retarding effect after twenty-four hours, and in Cases 3 and 4 the fasting blood sugar shows the prolonged effect of zinc-protamine-insulin to be greatly superior. Cases 5, 6, 7, and 9 are too mild to show any clear comparison, as the fasting blood sugar is nearly normal with all types of insulin; and in Case 8 the doses of insulin are insufficient to show any effect, and all the fasting blood-sugar concentrations are equally high. I regret to be so sweepingly critical, but I have considered all the nine cases. Moreover, a study of the blood sugar at three to six hours mostly shows the new compound to act more quickly and strongly than zinc-protamine-insulin. I believe my reading of the authors' figures to be fair. Protamine is cheap enough, and I doubt whether the point they make that tannic acid is cheaper still would count for much in their commercial price.—I am, etc.,

London, W.1, Feb. 21.

R. D. LAWRENCE.

After-effects of Modern Treatment of Carcinoma

SIR,—I was much interested in Mr. Percy Furnivall's description of the results of x-ray therapy as illustrated by his own personal experience (*Journal*, February 26, p. 450). I have often advised patients suffering from various forms of malignant disease to submit to x-ray treatment, and in a considerable proportion of cases the results, so far as the actual tumour is concerned, have been satisfactory. I have been dismayed, however, to note that all too often the general state of the patient after this form of treatment has been lamentable.

An early case of breast cancer in a woman in the late thirties was treated by surgery followed by repeated exposure to x rays. Two or three years after this treatment had ceased she presented the dried-up "wizened" appearance of a very old lady. She had been a particularly "alive" woman and strove frantically to keep in touch with her many interests, but her physical state proved too much for her and life became devoid of all interest. She lingered on for ten years, and then developed a tiny carcinoma in the shrunken remnant of the remaining breast. This was removed, but twelve months later there appeared many subcutaneous nodules and the patient died.

This case is an outstanding example of the devitalizing results which I have again and again seen following x-ray therapy, especially in cases in which repeated full doses of x rays have been administered. Radium beam therapy appears to be replacing to an increasing extent treatment by the insertion of radium, but I fear the effects of this method are likely to be as disastrous as prolonged x-ray therapy has sometimes been. My radiologist friends can tell me of no experimental work on animals which is being done with a view to discovering what effect on general well-being the exposure to repeated doses of x rays has on healthy individuals. I should be glad to know if any of your readers can give any information on this point. I feel sure that the best type of individual has little use for a life which is a mere existence, and if research should indicate that repeated exposure to x rays spread over a long period of time produces senility within a year or two, then probably this form of treatment should be discarded in favour of methods which get it "over and done with" quickly. It is known that ultra-violet rays produce senile changes, and there seems reason to fear that x rays do the same in a much greater degree.—I am, etc.,

Bradford, Feb. 26.

JAMES PHILLIPS.

Infantile Pyloric Stenosis

SIR,—Mr. David Levi, in his criticism (*Journal*, February 26, p. 486) of Dr. J. Vernon Braithwaite's communication on the treatment of infantile pyloric stenosis by antispasmodics (February 12, p. 334), would seem to have overlooked the fact that by the use of eumydrine or other antispasmodic, hospitalization of the infant, which, as he truly says, is fraught with no little danger, becomes unnecessary. Indeed, this to my mind is one of the great advantages of the eumydrine treatment. It is so simple that it can be easily carried out at home. It consists merely in the administration before the feeds, breast or bottle as the case may be, of the drug in an aqueous solution, in bulk amounting as a rule to no more than one teaspoonful.

I also think that Mr. Levi underestimates the effect of the eumydrine method of treatment. In my experience it is as good as any other, surgery not excepted. The last six examples of hypertrophic pyloric stenosis admitted

either by Mr. Harold Murphy, K.C., in his report, or by the Minister of Health in his recent letter to the Croydon Corporation. May one not add that most medical officers of health, when faced with such an epidemic, would welcome both the guidance and the support which they could obtain from such a committee?

Moreover, Sir, co-operation is not limited either in time or in direction. In any area there either is a co-operative spirit or there is not. The tragedy of Croydon was due to lack of co-operation and co-ordination not in one direction but in many. Do we want another Croydon? If not, then I suggest that it is the duty of all of us, both medical officers of health and general practitioners, to help to perfect the co-operation which would make another such tragedy impossible.—I am, etc.,

London, S.W.18, Feb. 28.

F. GRAY.

* The letter from the Ministry of Health to the Croydon Corporation will be found at page 530 this week.—ED., B.M.J.

Abortion and the Law

SIR,—In the recent discussion on "The Law relating to Abortion" (*Journal*, February 19, p. 408) Mr. Justice Humphreys stated that it was in 1837 that abortion was made a statutory criminal offence. This is not quite accurate. Two Acts of Parliament relating to abortion preceded the 1837 Act.

The first (43 Geo. III c. 58) was passed in 1803. By this Act the attempt to procure abortion on a woman quick with child by means of drugs was punishable by death, whereas if the woman were not quick with child the punishment was transportation or imprisonment, whether the attempt was made by drugs or instruments. There seems to have been a remarkable oversight, for the Act does not make it any crime to attempt to procure abortion on a woman quick with child by means of instruments. The first trial under this Act, known as Lord Ellenborough's Act, took place in 1811. The accused was charged with the administration of savin to a woman for the purpose of procuring abortion. He was acquitted. The next Act was passed in 1828 (9 Geo. IV c. 31). By this Act the offence was still a capital one if the woman were quick with child, but if she were not quick with child the crime was not punishable by death. Many pretty legal arguments took place over the exact meaning of the phrase "quick with child." This Act remedied the omission previously referred to.

Then followed the 1837 Act mentioned by Mr. Justice Humphreys, which altered the law in two important respects. There was now no distinction between women quick with child and women not quick with child, and the offence was no longer punishable with death. Finally the two Acts of 1861 and 1929 define the law on abortion at the present time. This last measure, the Infant Life Preservation Act, 1929, was passed to remedy a curious defect in our law, for while it was criminal to destroy a child by procuring abortion or to kill it directly after birth, Mr. Justice Talbot, in a case before him, held that it was no offence to cause the death of a child during the actual process of birth. The Act makes the procuring of abortion legal under certain circumstances—namely, that it is done to save the life of the mother and that the seventh month of pregnancy has been reached. This still leaves the main question of the legality of therapeutic abortion for preserving the life or health of the mother during the first seven months of pregnancy, or for preserving the health of the mother after seven months (for it is legalized only after seven months, and then only for

saving the life, not the health, of the mother), in an undecided state.

The law having defined certain circumstances under which it is legal to procure abortion, it may well be argued that, by implication, it may not be done under any other circumstances. Are we as safe from the hand of the law as Mr. Justice Humphreys suggests?—I am, etc.,

Hove, Feb. 20.

L. A. PARRY, F.R.C.S.

Oblique Osteotomy for Fracture of Neck of Femur

SIR,—I have read with interest the article by Mr. T. P. McMurray in the *Journal* of February 12 (p. 330), but I feel that some criticism is needed. Mr. McMurray describes the Smith-Petersen operation for the introduction of the Smith-Petersen pin. This is now out of date and has been superseded by other methods, one of the most popular being that of Mr. Ernest W. Hey Groves. I have had experience of this method in approximately one hundred cases. The three criticisms which Mr. McMurray levels at the Smith-Petersen operation can be considered in connexion with the Hey Groves method as follows:

(1) There is no operative shock with the Hey Groves method. The patient's general condition improves immediately the operation has been performed, and it can be carried out on patients up to 85 years of age without the slightest fear of complications. If patients can stand treatment at all they will stand this method. The time taken to operate is very short, and after it has been done several times the operator can manage with one x-ray only. (2) I have never seen the pin slip out when walking has begun. The date for the starting of walking is very important. People with decalcified bones should be kept in bed until there is bony union, although young patients with hard bones, between 15 and 40, can walk the next day. (3) In my experience disintegration of the small proximal fragment occurs only after an open operation when the capsule is opened and the blood supply to the head is further embarrassed. In none of my cases has it happened after operation by the closed method. Henderson's 25 per cent. of aseptic necrosis followed the open operation, using the Smith-Petersen incision.

In those cases in which the pin was correctly placed union took place in every instance. In those cases in which the pin was incorrectly placed—4 per cent.—the pin was removed and either reinserted correctly or else McMurray's osteotomy was performed. In cases of failure McMurray's osteotomy is of great value. In those cases which cannot be treated by the closed method because reduction cannot be obtained—this has occurred only twice in my experience—McMurray's osteotomy is performed. In my opinion the intracapsular fractures of the transcervical type are no longer a problem. It is much easier to produce perfect results in this type of fracture, by means of the Hey Groves technique, than it is in Colles's fracture in aged patients. There have been many discussions on this question of intracapsular fractures of the neck of the femur, and it would perhaps be advisable to leave the matter alone until surgeons have been able to collect sufficient cases to produce useful statistics.

Another argument in favour of blind intracapsular pinning is in regard to hospital beds. It would be impossible to treat these cases at hospital in plaster for three and a half months, and beds would not be available for such a length of time at any of the Bristol hospitals, since these fractures are numerous. In the Hey Groves method the patient can leave the hospital

the use of caps and chemicals has no tendency to induce sterility—often to the embarrassment of the clinic workers—and that not uncommonly cervices which when seen at the first examination were in a highly infected state clear up after the woman has been using a cap and chemicals for some months. Mr. Green-Armytage is the plaintiff in this case and the onus of proof lies on him. Without a control series of observations on nulliparous women who have used no contraceptives, and an estimate of the percentage of newly married couples (fertile and infertile) using contraceptives, he is expressing nothing more than a pious opinion. Information on this point is being collected by that most valuable body the Population Investigation Committee. We are fortunate in having Mr. A. C. Palmer as the chairman of the medical subcommittee of the N.B.C.A. and Mr. L. Carnac Rivett as a member. I may add that this subcommittee is not biased in favour of contraception, but was appointed in an attempt to safeguard the public, to investigate and evaluate contraceptive methods, appliances, and chemicals at present in use. The conclusions of this subcommittee are not merely conjectural but are based on direct clinical observation of thousands of cases and scientifically conducted experimental work. An effort is being made to arrive at the true facts without prejudice. Methods are submitted to controlled clinical trial; rubber appliances and chemical products are subjected to stringent tests for efficiency and harmlessness before they are placed on the list of approved goods. The subcommittee is at present engaged in an investigation of the effect of chemicals on the cervix, and would be extremely grateful for any relevant facts and figures which Mr. Green-Armytage might care to place at its disposal.—I am, etc.,

Crediton, Devon, Feb. 25. MARGARET C. N. JACKSON.

SIR.—My committee ask me to state that they have decided against publishing a detailed reply to Mr. Green-Armytage's statements about contraceptives. His assumptions appear to be too much a matter of opinion to be suitable for discussion in the Press. I am asked to remind your readers that our clinics are open to attendance by any medical practitioners, and that many thousands of case records are available for reference. The National Birth Control Association maintains that the teaching of contraception should be a matter essentially for the medical profession; and whilst not doubting that indifferent and harmful methods are sometimes employed by the public, it contends that our controlled methods in no way injure health or fertility. This conclusion is shared by all members of the association, including Lord Horder (president), Dr. C. P. Blacker, Mr. Aleck Bourne, Dr. Geoffrey Bourne, Professor F. J. Browne, Mr. Harold Chapple, Mr. C. Lane-Roberts, Sir Walter Langdon-Brown, Mr. A. C. Palmer, and Mr. L. Carnac Rivett.—I am, etc.,

M. A. PYKE,

69, Eccleston Square, S.W.1.
Feb. 28.

Secretary, National Birth
Control Association.

SIR.—It is regrettable that a question relating to the results of birth control in general should degenerate into an attempt to defend the proceedings of any particular society which exists for that proclaimed purpose.

Dr. Joan Malleon (February 26, p. 484) takes the extreme case of a recently married, pregnant woman, maintaining an unemployed husband, to justify the practice of immediate birth control on marriage; but does she really believe that equivalent justification exists in more than a very small fraction of the cases in which immediate birth control is applied? There are grounds for objection

to the insidious surrender of our racial strength to the short-sighted sympathies of birth control societies and their like, and to the profit-seeking activities of commercial companies.

The threat of war to an empty Empire and the economic difficulties which must arise during the shrinkage of our population are issues which ought to be realized now. The subject of birth control is one for national review and national policy, since it is nation-wide in prevalence and of Imperial concern. It is time for the control of birth control.—I am, etc.,

London, W.1, Feb. 27.

GEORGE H. ALABASTER.

SIR.—Surely it is unscientific to speak of "contraceptive measures" having this or that harmful physiological result without explicitly stating which measures were used and by which type of human subject. In 1923 (*Contraception, its Theory, History, and Practice*) I codified more than sixty physiologically, chemically, and physically different types of contraceptives, of many of which not less than hundreds of commercial brands exist. Many of these doubtless have the bad effects described by Mr. Green-Armytage, but it should not be forgotten that I laid down as the slogan of the pioneer birth control clinic—"Never put in the vagina what you would not put in your own mouth"—and hence the contraceptive measures used at the C.B.C. clinics do not have the bad effects attributed to "contraceptive measures," unspecified, by Mr. Green-Armytage.—I am, etc.,

C.B.C. Clinic, 108, Whitfield Street,
W.1, Feb. 23.

MARIE C. STOPES.

Co-operation

SIR.—It is very encouraging to find from Dr. Hugh Paul's letter in the *Journal* of February 26 (p. 480) that medical officers of health are giving practical consideration to the methods to be adopted if real co-operation is to be secured. Dr. Paul suggests that a consultative committee would be ineffective if summoned to assist the medical officer of health in an epidemic. This would certainly be the case if the committee met only on those unfortunate occasions; such a committee, somewhat overawed at its sudden importance, would be about as useful as the collection of "yes-men" that follow a Hollywood director and hang with bated breath on his dicta.

On the other hand, it must be evident to anyone who has considered the matter that a consultative committee, meeting whenever it was of advantage to have an exchange of views between the practitioners in an area and the public health officers, must be of the greatest value in securing the happy and successful development of the local health services. A committee, having gained in this way experience in times of peace, would find some useful part to play when war was suddenly declared on some local outbreak of disease.

Co-operation will not be secured merely by talking or writing on the subject; a little goodwill on both sides would soon see these local committees established.—I am, etc.,

London, W.10, Feb. 26.

HORACE A. NATHAN.

SIR.—Dr. Hugh Paul, in the *Journal* of February 26 (p. 480), suggests that a committee representing the general practitioners of a locality would be of no use in the presence of an actual epidemic of infectious disease. If we take the view, which Dr. Paul appears to hold, that a medical officer of health has nothing to learn from such a committee, then we must agree with Dr. Paul's suggestion. It seems, however, that this view is not accepted

Hyperventilation Attacks

SIR.—The hyperventilation attacks recorded by Drs. Russell Fraser and William Sargent in the *Journal* of February 19 (p. 378) recall to mind the case of a woman of 60 who suffered from "fainting fits" when a child.

Soon after the birth of her own child—she was then 35 years old—the developed attacks of tetany of her hands. When I first saw her four years ago I pointed out that her attacks only came on following hyperventilation, and I produced such an attack by forcing her to overbreathe. After that time the attacks became much less frequent. For the past four months I have prescribed acid, hydrochlor. dil., 5j t.d.s., and since that date she has had no further attacks, although previously these were occurring at roughly three-weekly intervals. The attacks were associated with emotional upsets. No attempt was made to deal with the emotional difficulties from the psychological side, and I believe suggestion may be ruled out by the failure of previous medicaments.

In view of the inability of Fraser and Sargent to obtain relief by acid administration I thought that this case might be worthy of report.—I am, etc.,

Ilford, Essex, Feb. 20.

R. N. C. SMITH.

Bug Destruction

SIR.—The article by Mr. S. A. Ashmore and Mr. A. W. McKenny Hughes on coal-tar naphtha for the destruction of bed-bugs in your issue of January 22 will be of great interest to all those connected with public health work. In a previous article on bed-bug control (*Lancet*, May 1, 1937) I made several criticisms of heavy naphtha. While it is now certain that heavy naphtha can be used with safety by the operator (apart from fire risk) and that it is successful in killing adult bugs and nymphs in exposed positions, attention must be drawn to the fact that it is far less toxic to eggs.

The following table shows the toxicity of heavy naphtha, conforming to the published specifications, to eggs laid by bugs reared at 73° F. in this laboratory. The eggs were exposed in wide glass tubes to the saturated air above heavy naphtha in air-tight desiccators. The number of eggs used for each test was approximately fifty and the temperature of fumigation 73° F. After exposure the eggs were removed and kept at the same temperature for observation.

Exposure Time to Saturated Air	Percentage Hatch	Percentage of Nymphs Alive after 18 Days
Controls	97	90
2½ hours' exposure	96	75
15 " "	38	17
24 " "	0*	0

* Six nymphs died on hatching.

When eggs were exposed to air saturated with heavy naphtha at 55° to 65° F. in a desiccator left in the laboratory a complete kill was not obtained even after twenty-four hours' exposure—a 7 per cent. hatch being obtained.

The conditions of test were undoubtedly in favour of the fumigant, as it would be impossible in practice to maintain such concentrations of vapour in dwelling houses. The concentration of naphtha (vol./vol. with air) which can be obtained at 60° F., according to Ashmore and McKenny Hughes in Table I of their article, is of the order of 0.20 per cent., and this was found by them to be lethal to all bugs exposed for twenty-four hours, and a complete kill was ultimately effected with a concentration of 0.10 per cent., although neither the number of insects used nor the temperature during the test was specified (Table II).

It is stated that the concentrations applied equally to eggs, but it is extremely doubtful if a concentration of 0.20 per cent. at 60° F., as estimated on samples of air taken from premises under gas, would be effective in killing eggs concealed behind wainscoting, since a 7 per cent. hatch was obtained under ideal conditions in a sealed desiccator at approximately this temperature after twenty-four hours' exposure. Even at a concentration of 0.25 per cent., obtained with the delayed-action sprinkler, only a small margin of safety is left, and would probably only be completely successful in killing those eggs laid in unconcealed places.

The fact that naphtha is far more effective against the adults and nymphs than against the eggs is contrasted with the behaviour of hydrogen cyanide, which is slightly more toxic to the latter. The belief that eggs were far more resistant than the other stages to hydrogen cyanide is due to the fact that they are often not so well exposed to the fumigant, being laid in concealed places and sometimes protected by cast skins, etc.

Field tests carried out by me with heavy naphtha in six badly infested houses in St. Pancras during June, 1937, have shown that when used in the amount stated—namely, 1 gallon per 750 cu. ft.—a 20 per cent. hatch was obtained from eggs in open tubes exposed to the full action of the vapour in different rooms for a period of twenty-six hours at a temperature of 65° to 70° F. In fairness it must be stated that the premises were in a very bad condition, but much time had been spent in making them as air-tight as possible. The delayed-action sprinkler was not at that date available, but the walls were festooned with blankets and hessian on to which the majority of the naphtha was sprayed.

Although several dozen bugs were collected from the floors of these houses, having dropped from behind the wall-paper above the skirting-boards during fumigation, only one recovered. However, when wall-fittings such as gas-bracket supports were removed live bugs were found behind. The fact that naphtha sometimes fails to kill bugs in such places suggests that in all cases the premises should be stripped.

One of the chief items of expenditure in bed-bug disinfection work is the cost of redecorating and repairing premises. In all contact insecticide disinfection, to be certain of killing all bugs with a single spraying loose wall-paper must be thoroughly stripped and all skirting-boards and picture rails removed or eased away from the walls. If this is unnecessary when using heavy naphtha it is an important point and may outweigh other disadvantages, such as the cost of preparing, sealing, and pre-heating. Although heavy naphtha is relatively cheap the cost of material will be considerable if the full dosage as recommended is to be adhered to—namely, 1 gallon per 750 cu. ft. (500 cu. ft. in furnished houses). In addition, another half-gallon or one gallon is to be sprayed by means of the delayed-action sprinkler on to the cotton screens. The total amount necessary may then become of the order of three to four gallons per room.

The table below gives the disinfection costs of six unoccupied houses in a terrace in St. Pancras. Each house consisted of three floors and a basement, with a total of eight rooms. The total time spent in the preparation of the premises—removing skirting-boards and some floor boards, stripping wall-paper, etc., sealing premises, and subsequent fumigation—was fifteen working days: 163 gallons of heavy naphtha were used—an average of twenty-seven gallons per house.

	£	s.	d.
Cost of naphtha at 2s. per gallon	16	4	0
Materials used for sealing of premises: matchboarding, gummed rolls, etc.	5	8	0
Equipment: pump, gas masks, torches, screening material, etc., 2½% of cost	3	6	0
Wages and expenses of three men for 15 working days	30	12	11
Hire of lorry	1	15	0
	£57	5	11

on the fourteenth day and in some cases need not be in hospital longer than three weeks from the date of admission. Cases can be treated in this way even when they arrive at the hospital with bed-sores, since early ambulatory treatment following the pinning operation allows the bed-sores to heal.—I am, etc.,

KENNETH H. PRIDIE,
Assistant Orthopaedic Surgeon,
Bristol Royal Infirmary.

Fracture Clinic, Bristol
Royal Infirmary, Feb. 24.

Ascorbic Acid in Urine

SIR,—In an interesting article by Dr. G. W. T. H. Fleming and Dr. T. E. Burrows (*Journal*, February 12, p. 333) on the relative efficiency of acetic and sulphuric acids for the preservation of the ascorbic acid excreted in urine, the conclusion is reached that because sulphuric acid rapidly destroys any ascorbic acid added to water or urine the use of sulphuric acid for clinical purposes is of very doubtful value. This would appear to be contrary to the findings of several workers who have carried out investigations on vitamin C excretion using sulphuric acid as a preservative and state that little or no loss of vitamin occurs when the urine is kept for twenty-four hours. My own experience has shown that the original reducing power of the urine can be better preserved by the addition of 2 per cent. sulphuric acid than by 5 per cent. acetic acid. In the following table taken from my notes it will be seen that in six experiments with sulphuric acid the amount of titrable substance remained fairly constant over a period of twenty-four hours (the slight increase in some specimens may be due to a gradual darkening produced in concentrated urines by sulphuric acid), whereas there was a marked decrease in this substance with 5 per cent. acetic acid. Each specimen of urine immediately after voiding was divided into two parts; 2 per cent. sulphuric acid was added to one part and 5 per cent. acetic acid to the other. Titration was carried out according to the method of Birch *et al.* (1933) using a microburette.

Specimen of Urine No.	Reducing Substance in mg. per cent.			
	Acetic Acid 5%		Sulphuric Acid 2%	
	After 1 hr.	After 24 hrs.	After 1 hr.	After 24 hrs.
1	3.1	2.0	4.0	4.4
2	3.4	2.1	4.5	4.4
3	3.0	2.0	4.2	4.5
4	2.5	1.9	3.4	4.2
5	1.8	1.2	2.3	2.3
6	2.5	1.4	3.1	3.1

Although it is doubtful whether the reducing substance estimated in urine treated with sulphuric acid is entirely a product of ascorbic acid, it appears reasonable to assume that for general diagnostic purposes the results are sufficiently reliable. There is no doubt, however, that when greater accuracy is desired the urine must be titrated immediately it is passed.—I am, etc.,

FREDERICK T. THORPE.
Wadsley Mental Hospital, Sheffield, Feb. 21.

SIR,—Drs. G. W. T. H. Fleming and T. E. Burrows, in their paper on a possible discrepancy in the estimation of ascorbic acid in urine published in the *Journal* of February 12 (p.333), raise questions which lie more in

the province of the analytical or bio-chemist. There are opinions expressed in the paper, however, which invite a more general criticism.

In an earlier part they state that "some workers appear to be aware of the destruction of ascorbic acid by sulphuric acid," and in the summary that "sulphuric acid has been shown to destroy ascorbic acid." Both statements are misleading in their assumption that sulphuric acid is the "destroyer." It is well known that ascorbic acid is rapidly oxidized in aqueous and in alkaline solutions to substances which do not reduce indophenol. The authors themselves have found that the loss of ascorbic acid in solution in water is 100 per cent. in twenty-four hours. Would they say, in this case, that water was the destructive agent? Surely the process involved is oxidation, aided in some instances by traces of copper in the water or organic fluids acting as a catalyst. Van Eekelen (1934) has found that the indophenol-reducing power of urine is actually increased by boiling with 5 per cent. sulphuric acid in an atmosphere of carbon dioxide for fifteen minutes. Later the efficacy of acetic acid as a preservative of ascorbic acid in urine is questioned, when Drs. Fleming and Burrows say "even with acetic acid there is such a destruction of ascorbic acid that it is quite obvious the results obtained will be of very doubtful value." Much clinical research has been done using this very method. Harris (1935) has already stated that the loss of ascorbic acid from urine, on the addition of 5 per cent. glacial acetic acid, is 20 to 30 per cent. in twelve to fifteen hours, but is of opinion that "this loss is generally of little practical significance." There are other possible channels of excretion—sweat and faeces—of ascorbic acid, which his method does not take into account, and he makes no claim that the urinary output of ascorbic acid is a measure of the total metabolism of vitamin C in the body. An average finding, using Harris's technique, is that a healthy adult excretes 35 mg. of ascorbic acid in the urine in twenty-four hours. In the twenty-four hours following the administration of a test dose of 700 mg. of ascorbic acid this will rise to 450 mg. At the other end of the scale the corresponding figures for an adult with scurvy might well be 5 mg. and 7.5 mg. Let the authors add their own average loss of ascorbic acid in presence of acetic acid (20 per cent.) to the above, and they will see that the results are still of the same comparative order of values. The advantage of the test dose is that it magnifies the relatively small differences seen in the "resting-levels," especially when these are low or sub-normal. Thus the 20 per cent. loss of ascorbic acid in urine preserved with acetic acid becomes of less importance.

A recent investigation by Scarborough and Stewart (1937) has shown that acid hydrolysis increases the indophenol-reducing power of urine, and this increase is due to the production of extra ascorbic acid, which is present in the urine partly in a reduced form, partly as dehydro-ascorbic acid, and as hydrolysable derivatives of these substances. Some degree of hydrolysis on the part of sulphuric acid may possibly explain the differences that Drs. Fleming and Burrows have found between their results with sulphuric acid and those obtained with acetic acid.—I am, etc.,

R. HARDY.

Obituary

A. DOUGLAS BIGLAND, M.D., F.R.C.P.

Physician, Liverpool Royal Infirmary

We regret to announce the death on February 20 of Dr. Douglas Bigland, who had been honorary physician to the Liverpool Royal Infirmary since September, 1934.

Alfred Douglas Bigland, son of the late Alfred Bigland, M.P., was born at Birkenhead in 1887, and from Birkenhead School went to Caius College, Cambridge, taking his B.A. in the Natural Sciences Tripos. He studied medicine at Liverpool, graduating M.B. and Ch.B. Liverp. in 1912, and M.D. soon afterwards. He obtained the M.R.C.P. Lond. in 1919, and was elected F.R.C.P. in 1935. He had been house-physician at the Liverpool Royal Infirmary, and was appointed medical tutor and registrar in 1914, but after the outbreak of war he joined the R.A.M.C. with a temporary commission and served in France, at Suvla Bay, and in Egypt. On returning to civil life in Liverpool Dr. Bigland was appointed lecturer in clinical medicine at the University, and built up a considerable practice. For some years he was honorary physician and medical officer in charge of the neurological department of the David Lewis Northern Hospital, and before his promotion to the senior visiting staff at the Royal Infirmary, caused by the retirement of Dr. J. C. Matthews, he had been honorary physician to out-patients. His other appointments included those of honorary consulting physician to the Lancashire Mental Hospital, Rainhill, and to the Home for Epileptics, Maghull. Dr. Bigland was an active member of the Liverpool Medical Institution and of the Association of Physicians of Great Britain and Ireland, and contributed several papers to the *Lancet* and the *British Medical Journal*. He acted as sectional editor of the Tropical Diseases Bureau, covering the subject of pellagra. In later years he became very interested in asthma, and established a flourishing asthma clinic at the Royal Infirmary.

Dr. Robert Coope writes:

The death of Dr. Douglas Bigland at the age of 51 came after many years of chronic illness. For the past year it was clear to his friends that he was seriously ill, and in the last six months he was largely confined to his house, hoping that he might recover sufficiently to get back to his hospital and consulting practice. In 1923 he became assistant physician to the Liverpool Royal Infirmary, acting as junior colleague first to the late Dr. John Owen and later to Professor John Hay. The rigours of his war service brought on an illness which was ever afterwards to hamper his career, prevent him from developing his full powers, and by its interruptions to his consulting work place him in a position of insecurity and finally cause his death. In 1930 his first wife, Dr. Phoebe Powell Bigland, died after a long illness; shortly after he himself fell ill again, and he had to spend the best part of two years lying on his back. He returned to work again, and in 1934 was elected to a full physicianship at the Royal Infirmary.

He was a most lovable person. *Souffrir passe; avoir souffert ne passe jamais*; his suffering refined and mellowed him to a rare gentleness, and to the end he retained a brave, gay, and lovely spirit. He had learned to enjoy and treasure what he felt were the important things—to do his work to the best of his ability, to earn the gratitude

and confidence of his patients, and to possess the respect and friendship of his students and colleagues. He had long made his peace with the limitations which his illness forced upon him; he had a grand courage to go on as long as ever he could and to accept the fact that he could not do all he wished to do. He was a sound clinician, proud to follow in the clinical tradition of his old teacher, Dr. John Hill Abram, whom he often quoted. To him the patient always came first, and he deliberately made time for those little personal touches which made his patients feel that while he was with them his care and thought were entirely for them individually. He was a good teacher, simple and direct. Perhaps he was at his best at his hospital ward rounds, for in spite of his serious sense of responsibility to patients and students he had a great sense of fun, which bubbled up to the delight of patient, nurses, and students alike. But the peals of merriment which at times interrupted the decorum of a formal ward visit brought confidence to the patient and usually rammed home for the student some fundamental piece of clinical knowledge. A little over three years ago he married again, and to his wife and the two daughters of his first marriage goes out the sympathy of his many friends.

DENIS A. SHEAHAN, M.D., M.Ch.

Dr. Denis A. Sheahan was born at Drinagh, Buttevant, Co. Cork, in 1861, the eldest son of Timothy Sheahan. He studied medicine at the Queen's College, Cork, and at Dublin, and obtained the degrees M.D., M.Ch. of the Royal University of Ireland in 1884 and the M.A.O. in 1885. He practised for a short time at Oswestry in Shropshire and later in London. In 1888 he was appointed medical officer to Portsmouth Dockyard, and set up in practice for himself in Commercial Road in the city, and by assiduous attention to his professional duties he quickly established a very extensive practice and remained there for nearly forty-five years, retiring in 1931. During the time he was in Portsmouth he was well known throughout the city for his great kindness to his patients, and to the citizens in general for his uprightness and high sense of honour. He gave very freely of his services, and his zeal for the welfare of his patients and his capacity for taking pains earned for him the esteem of all those who sought his aid and advice. He truly never spared himself, being constantly—both by night as well as by day—at the service of those who needed him. Dr. Sheahan joined the British Medical Association fifty-one years ago, and was an active member of the Portsmouth Division. He represented the Southern Branch of the Association on the Council from 1918 to 1924, and acted as representative in the Representative Body from 1915 to 1924, his work and energy in this capacity being much appreciated by the members of the executive and by his colleagues in the Division. He was medical officer for the prevention of cruelty to children for many years, and in this work he took much interest, his love and his sympathy for little children being a great stimulus in helping him to alleviate the sufferings of the less fortunate among them.

Dr. Sheahan (writes a colleague) had great power as a raconteur; his native wit and readiness in repartee on many occasions caused much amusement to those with whom he came in contact. He was a keen student of Nature, and was frequently to be seen during a few leisure hours on a Sunday afternoon strolling in the country lanes or in the fields. It is perhaps difficult to imagine the pleasure and the ecstasy which he derived from observing the workings of the bee or the butterfly, or the

The foregoing figures do not take into account the cost of technical supervision of the work.

There is no doubt that the dilapidated state of the houses was the chief reason for the high cost of their disinfection, since a considerable time was spent in rendering them relatively gas-tight. Although the cost of naphtha was a considerable item in the expense the labour cost is also very considerable, and it would be of great value to public health authorities to be given detailed costings of actual disinfections by the naphtha process.

There is no doubt that the heavy naphtha process is a much safer method of disinfection of vacated properties than hydrogen cyanide. On the other hand, it cannot be applied to occupied dwellings, particularly tenements tenanted by several families. In such cases an efficient contact insecticide, if properly applied by an electric or other suitable sprayer, can be used with complete safety and success. It is, however, important that the insecticide used should not only kill adults and nymphs but should also be highly effective as an ovicide. Practical experience has shown that the process is very economical in time and material, and, above all, thorough disinfection can undoubtedly be achieved.—I am, etc.,

Otitis Externa

SIR,—I read with interest the article on "hot-weather ear" by Flight Lieutenant George Morley in the *Journal* of February 19 (p. 373). During fifteen years of practice in Hong Kong I came across many cases of otitis externa caused by *B. pyocyaneus*, often as a result of bathing in sea water which was contaminated by sewage. I found that treatment with an autogenous vaccine alone, without any local application, cleared up most of these cases. In this condition it is often difficult to introduce a preparation into the ear on account of the extreme swelling, which may completely occlude the meatus.—I am, etc.,

London, W.1, Feb. 22.

J. C. MACGOWN.

Correct Footwear

SIR,—I am surprised that none of your recent correspondents has drawn attention to the fact that practically the whole range of deformities and disabilities of the feet seen in adult life, and often present in aggravated form in women patients, are to be discovered on systematic examination of young children's feet. Routine examination in toddlers' clinics of infants from the age of 2 upwards has disclosed conditions which undoubtedly are due to the wearing of incorrect shoes at this age and are not self-correcting but generally escape notice unless looked for, because of the absence of associated discomfort when the feet are still very young and pliant.

School children's feet (examined barefoot) confirm the existence and persistence of these deformities, and the fact of their prevalence, though complaints of pain and weakness continue to be rare during school life. The earliest and commonest premonitory defect is a deflection outwards of the terminal phalanx of the great toe (produced by too short shoes or shoes with a too rounded toe), and the mechanism which subsequently produces ingrowing toenail, hammer-toe, overlapping outer toes, hallux valgus, spreading of the anterior arches, and corns or blisters, in the young child, is quite clear to those who look and think the matter out. Valgus heel and flat-foot proper may follow from other defects in the type of shoe used or from a combination of bad shoeing with other conditions.

Appearance and efficiency demand that such a widespread departure from perfect form and functioning should

not be left to take its chance amongst the ills to which we become accustomed in "civilized" life. It is obviously useless to tackle a problem of this kind by concentrating on the adult, and I would heartily support those who say that it can only be put right by providing correct lasts and fittings for the generality of the population by willing co-operation of our own profession with the shoe-producing trade. It is we who have stood by and let deformities develop, not seeking to educate the manufacturers on fundamental points, and it is we—not the vain of either sex—who must bear the responsibility if the conditions causing deformity are allowed to continue. Let us combine and secure for the coming generations "physically fit" feet by applying our scientific knowledge to the care of the feet from babyhood.—I am, etc.,

London, S.W.1, Feb. 22.

MARGARET EMSLIE.

Early Diagnosis of Pulmonary Tuberculosis

SIR,—According to Dr. Geoffrey Marshall (*Journal*, December 4, 1937, p. 1103), "When the patient comes to the specialist it is usually because there has been some conclusive symptom, or because an examination of the sputum or an x-ray photograph of the chest has established the diagnosis." To the general practitioner and those less conversant with the study of radiology the final words of such a statement might be rather misleading; and I feel sure that what was implied must have been: "... some conclusive symptom, or because an examination of the sputum together with an x-ray examination of the chest has established the diagnosis." There is no question that an x-ray examination is a most essential link in the chain of clinical evidence, but an x-ray film can in no way be considered a photograph. If it were so many of our difficulties would be at an end. Dr. Geoffrey Marshall agrees that a lesion found during x-ray examination of the chest should immediately indicate the necessity for further investigations to prove the existence of the tubercle bacillus as the causative organism, and that a diagnosis based on radiology alone is, to say the least, most unwise. Yet every radiologist is familiar with the question—"Is it tuberculosis?" I consider that the most significant remark in Dr. Marshall's address is: "The wise physician will view and discuss these appearances with the radiologist; the wise radiologist will leave the responsibility of diagnosis to the physician." To this I would add "and to the pathologist."—I am, etc.,

Sydney, Australia, Jan. 20.

D. G. MAITLAND.

Pure English

SIR,—Feeling certain qualms for previous frequent use of the anomalous word "sympathicolytic," I recently took to using what must seem to etymological analysts the more correct form—namely, "sympatholytic." I find that this has been criticized. As the clinician has an interest in the term as well as the physiologist, I hope you will permit me to attempt to justify the use of the shorter word. It is a compound of three Greek words, *σῖν*, *πάθος*, and *λύσις* (anglicized lysis). The French use the word *sympatholytique*. Taking the root "patho-" of the middle word they logically add the suffix at once. Sympathetic in French nomenclature is *sympathique*, and consequently they with more reason than the English might have inserted an *ico* or *ique* between root and suffix. Where does *ico* come from in the English compound? If necessary to make an insertion let it at least be *etico*.—I am, etc.,

Cork, Feb. 18.

D. T. BARRY.

Medical Notes in Parliament

In the House of Lords on March 1 the Blind Persons Bill and the Population Statistics Bill were read the second time. The Poor Law (Amendment) (No. 2) Bill passed through committee, and the National Health Insurance (Amendment) Bill was brought from the Commons and read a first time. On the same day Lord Strabolgi introduced a Bill for the registration of hairdressers and to regulate the practice of hairdressing, and it was read a first time.

The Parliamentary Medical Committee met on March 1, Sir Francis Fremantle in the chair. The committee agreed to ascertain when the Ministry of Health Estimates would be discussed and to discover whether a whole day could be given to a debate on the health aspects of this Vote. The committee also considered an inquiry to learn whether the Minister of Health would institute a financial inquiry into the claim by the dental profession that an extension of dental treatment, especially of adolescents, would repay the Government.

The Conservative Parliamentary Agricultural Committee, meeting at the House of Commons on March 1, discussed the policy of the British Medical Association on milk. The committee thanked the Minister of Agriculture for his statement on the advertisements of the B.M.A. regarding milk pasteurization. According to a statement authorized by the committee, Mr. Morrison had characterized these advertisements as a distortion of the facts. It was stated to the committee that the Association's advertisements still appeared in certain journals and in certain milk shops, and that the Minister should be asked what further corrective measures could be taken. Professor Basil Buxton of the Royal Veterinary College then addressed the committee on the recent outbreak of foot-and-mouth disease. He remarked on its virulent character, and said at one time there seemed a likelihood that the disease might become endemic, with similar disastrous results to those on the Continent. Britain had been spared that calamity. He supported the policy of slaughter.

The second reading of the Increase of Rent and Mortgage Interest (Restrictions) Bill, which proposes to modify the rent restrictions on some classes of houses, was down for second reading in the House of Commons on March 2, and the committee stage of the Housing (Financial Provisions) Bill was set down for the following day.

Health and Medical Services in the West Indies

On February 23 the House of Lords debated the conditions in the West Indian colonies. During the discussion Lord OLIVER said the infant death rate in Barbadoes was now rather better because infant clinics had been set up and the people fed their children more sensibly. Barbadoes and "all those places" were riddled with infantile paralysis, which was simply a poverty disease. Earl FORTESCUE, replying for the Government, said the main deficiencies in the nutrition of the West Indian labouring classes were in animal proteins and vitamins, and the main reasons were poverty and ignorance. Much could be done by propaganda and instruction in schools to dispel the ignorance.

During the discussion by the House of Commons in Committee of Supply, on February 28, of the Vote on Account for the Civil Estimates Mr. ORMSBY GORE said that the whole organization of the medical department in Trinidad had got to be improved, and improved quickly. It was impossible to allow doctors who were carrying out their duty to the State of insisting on the standards laid down by the State with regard to housing and sanitation to be at the same time in private practice and in receipt of private fees, either from employers or anybody else. He would be accused of forcing

D.P.H. men and the like on the Colony, but he was determined to do it. It was essential that the major recommendations of the Commission's report should be carried out.

Dental Health of the Community

On February 23 at the House of Commons the Health and Housing Committee of Conservative Members received a deputation on the dental condition of the people. It was led by Mr. B. E. Astbury, general secretary of the Charity Organization Society, and by Mr. Grant of the National Dental Aid Fund. Mr. ASTBURY said applications to the Charity Organization Society for dental treatment had increased in a few years by 60 per cent., but no public appeal had been practicable. Proper dental care could save much of the £2,000,000 bill for drugs, but the Ministry of Health said no further money was available for such purposes. Mr. Astbury proposed that, as a beginning, there should be a thorough dental inspection before the entry of a boy or girl into employment insurance benefit. He said much social work, such as the maintenance of rheumatism clinics, was made necessary by neglect of teeth. He held that more should be spent from the national health insurance funds on dental fitness, and he pointed out that under the national physical fitness scheme nothing was to be spent on teeth.

Mr. GRANT said three-fourths of the industrial population had dental defects. The Prudential Society said that half the sickness of the industrial population—especially rheumatism, tuberculosis, and cancer—was due to teeth. He wished dental treatment to be continued after school.

Scottish Voluntary Hospitals

On March 1 Mr. ELLIOT, replying to Mr. Kennedy, said he was aware that some of the Scottish voluntary hospitals had financial difficulties, but there was no evidence that the voluntary system as a whole was unable to meet its commitments. The many important and difficult problems involved in the report of the Committee on Health Services, published in 1936, were being carefully examined, but he was not in a position to make a statement. Replying to Mr. Gallacher on the same date Mr. Elliot said no request for financial assistance from the Buckhaven Hospital, Fife, had yet reached him. There was no provision under which he could give assistance towards its maintenance.

Nutrition of the South African Native

Mr. MACDONALD, replying to Mr. Leach on March 1, said he had seen a Press report of the evidence given by Dr. E. H. Cluver, deputy chief health officer of the Union, to the Native Labour Committee in South Africa that three-quarters of the native population was underfed and that tuberculosis was increasing. Active steps were being taken to improve the diet of the natives in the High Commission Territories, such as an extensive scheme in Basutoland to promote the cultivation of vegetables, and in Bechuanaland the expenditure of large sums of money to improve the water supplies and the teaching of the value of green foodstuffs. The question of nutrition in these Territories was being examined by the committee of the Economic Advisory Council appointed to advise on nutritional matters in the Colonial dependencies generally. The position with regard to tuberculosis, which was closely linked with the problem of nutrition, was being carefully watched.

Rehousing of Tuberculous Persons.—Miss WILKINSON, on February 24, asked the Minister of Health to consider making provision in the new Housing Bill for a special subsidy to local authorities for the rehousing of persons suffering from tuberculosis who lived under housing conditions prejudicial to their health. Sir KINGSLEY WOOD answered that under existing Housing Acts local authorities could provide houses for persons suffering from tuberculosis. Any houses so provided obtained the benefit of the existing subsidies. In addition, the authorities might grant rebates from rent in suitable cases. He did not consider any special subsidy necessary.

swallow or the stoat. Indeed one felt of him that he was thus "never less alone than when alone" observing and meditating on the beautiful works of the Creator so wonderfully portrayed. He died at his home in Portsmouth on February 3, and in accordance with his lifelong wish his remains were conveyed to Ireland, and he was buried in the churchyard at Lisgriffin, Buttevant.

We much regret to announce the death of Dr. J. F. WALKER of Southend-on-Sea, who among many activities in the British Medical Association, both local and central, was chairman of the Charities Committee at headquarters for ten years. An obituary notice will appear later.

The Services

THE KEOGH BANNER

Ceremony at R.A.M. College

An interesting ceremony took place in the Library of the Royal Army Medical College on February 18 on the occasion of the unveiling of the Banner and Crest of the Knight Grand Cross of the Order of the Bath which had been bequeathed to the College by the late Sir Alfred Keogh.

The Director-General (Lieutenant-General Sir James Hartigan, K.C.B.) welcomed the assembly to the unveiling by Lady Keogh of the Banner bequeathed by her distinguished husband, which had until recently hung in the Henry VII Chapel in Westminster Abbey. It was particularly appropriate that the Banner should find its resting-place in the College, as it was largely due to the foresight and initiative of Sir Alfred that the College was first established. It was unnecessary to refer in any detail to Sir Alfred Keogh's career, but he would venture to express the opinion that to no other person did the corps owe so much. (Applause.) He was Director-General first, from 1905 to 1910, a time of great activity in the reorganization of the Army. During that period the College was built and opened, and postgraduate teaching was introduced into the Service; the Army School of Hygiene was first established, and the Territorial Army Medical Service was brought into being. His second period of office was during the great war, and it was a fact now recognized by all that both the Army and the nation were fortunate in having at the head of their Medical Services in that period an officer of such outstanding administrative ability. It was fitting, Sir James Hartigan continued, that they should honour a great man, and he would like to assure Lady Keogh that the memory of her most distinguished husband was held in the highest esteem by all ranks of the Royal Army Medical Corps. They rejoiced to think that the new barracks at Aldershot had been named the Keogh Barracks.

Lady Keogh pulled a silken cord revealing the Banner, charged with the late Sir Alfred Keogh's Coat of Arms—Or, a lion rampant, gules, surmounted by his crest, the whole being hermetically sealed in a stout oak frame with plate glass. Lady Keogh after the unveiling said: "Just before my husband died he told me that he wished his banner to go to this mess. I hope that it will remind you and future generations of all he did for his corps. From the time he was made a member of the Reorganization Committee in 1901 he never ceased to use all his energy and the whole force of his character to helping to make the Royal Army Medical Corps into a thoroughly scientific and efficient branch of the Army, and it is only recently, since I have been going through old letters and papers, that I realize what an uphill and arduous task he had—at any rate during his first years at the War Office. He never spoke of his work at home. He never spared himself, and he was completely without

personal ambition; but he thought no honour too great for the corps of which he was proud and in which he had great faith. Just before he died he said: 'I loved the soldier—he is the best fellow in the world, and I have done my best for him.' He said what had been the leading principle of his life. I wonder if any man could have faced that terrible war if he had not felt certain that if he were wounded or ill he would have all the skill and care that modern medical science could give. I am happy to think that my husband was at the head of that humane and courageous body of men who, as a dear friend of his wrote, alleviated and repaired the damage of war."

The Commandant (Major-General W. P. MacArthur, C.B.) accepted the Banner and Crest on behalf of the Royal Army Medical College and thanked Lady Keogh for unveiling the Banner: "An act which makes the ceremony a memorable occasion to us all."

MENTIONS IN DISPATCHES

The names of Major-General N. H. Hamilton, C.B., C.I.E., C.B.E., D.S.O., I.M.S., Colonel R. E. U. Newman, O.B.E., M.C., late R.A.M.C., Lieutenant-Colonel R. K. Mallam, O.B.E., R.A.M.C., Lieutenant-Colonel P. J. Ryan, M.C., R.A.M.C., Lieutenant-Colonel S. Arnott, R.A.M.C., Major J. D'A. Champney, R.A.M.C., Major T. W. Davidson, R.A.M.C., Colonel A. A. McNeight, I.M.S., Lieutenant-Colonel R. N. Khosla, I.M.S., Captain G. K. Graham, I.M.S., Captain M. M. Mansfield, I.M.S., Captain V. M. Albuquerque, I.M.S., Captain M. G. Leane, I.M.S., Captain R. B. Davis, I.M.S., and Captain T. Kapur, I.M.S., have been brought to notice by His Excellency the Commander-in-Chief in India for distinguished services rendered in connexion with the operations in Waziristan, North-West Frontier of India, January 17 to September 15, 1937.

The names of Major D. G. Sukumar, I.M.S., Captain W. F. Cooper, I.M.S., and Lieutenant P. W. Suraj, I.M.S., have been brought to notice by His Excellency the Commander-in-Chief in India for distinguished services rendered in connexion with the operations in Waziristan, North-West Frontier of India, November 25, 1936, to January 16, 1937.

Universities and Colleges

UNIVERSITY OF OXFORD

Miss Jean Orr-Ewing, B.M., B.Ch., has been appointed to a Tutorship in Natural Science at Lady Margaret Hall.

UNIVERSITY OF LONDON

At a meeting of the Senate held on February 23, Mr. R. S. Pilcher, M.S., F.R.C.S., was appointed as from October 1 to the University Chair of Surgery tenable at University College Hospital Medical School.

The title of Professor Emeritus of Pathology in the University was conferred on Dr. A. E. Boycott, F.R.C.P., F.R.S., formerly Graham Professor of Pathology at University College Hospital Medical School.

Mr. Herbert Lightfoot Eason, M.D., M.S., F.R.C.S., Principal (late Vice-Chancellor) of the University of London, Professor Edward Mapother, M.D., F.R.C.P., F.R.C.S., Medical Superintendent and Professor of Psychiatry, Maudsley Hospital, and Mr. Clifford Sidney White, M.D., F.R.C.P., F.R.C.S., F.C.C.O.G., Senior Obstetric Surgeon, University College Hospital, were elected to the Fellowship of University College, London.

A special University Lecture in physiology on "Some Remarks on Vestibular Physiology" will be given at University College, Gower Street, W.C., by Dr. A. P. H. A. D. Kleijn, professor of rhinology, laryngology, and otology in the University of Amsterdam, on Tuesday, March 15, at 5 p.m. The lecture, which will be delivered in English, has been arranged under a scheme for the exchange of lecturers between England and Holland. It is addressed to students of the University and to others interested in the subject, and will be illustrated with lantern slides. Admission is free, without ticket.

EPIDEMIOLOGICAL NOTES

Diphtheria and Scarlet Fever

There has been a decided decline in the incidence of both scarlet fever and diphtheria for all five countries from which returns of notifications are made, with the single exception of scarlet fever in Scotland, where notifications rose from 471 in the previous week to 490 in the week under review. The chief increases were found in Edinburgh, where 43 (33) cases were notified during the week under review, Renfrew county 18 (7), Lanark county 22 (11). The figures in parentheses denote the numbers notified in the previous week. During the week there were in Scotland no deaths from scarlet fever.

Measles

During the week under review deaths in the 125 great towns numbered 31 compared with 40 in the previous week, the principal towns affected being Greater London 6 (7), administrative county of London 5 (6), Liverpool 4 (15), Manchester 3 (6), Bristol 1 (2). The figures in parentheses denote the deaths in the previous week. During the week 1,551 cases were reported from the L.C.C. elementary schools, compared with 1,417 in the previous week. The average daily admissions to the L.C.C. fever hospitals were 61, compared with 53 for the previous week, and the number of measles patients in the L.C.C. fever hospitals on February 25 was 1,361, compared with 1,168 in the previous week. Details of notifications are available for Bermondsey 25, Stepney 34, Shoreditch 2. Particulars of the conditions of notification in the London boroughs where compulsory notification is in force were given on this page in last week's issue.

In Scotland notifications of measles rose from 1,551 to 1,691, while the deaths for the whole country declined from 20 to 15. Increases of notifications of measles were chiefly seen in Glasgow 1,345 (1,245), in Dundee 47 (38), in Paisley 74 (44); while decreases were noticed in Edinburgh 102 (121), Aberdeen 8 (10). The deaths from measles for the week were: in Glasgow 12, Edinburgh 2, and Dundee 1, compared with 17, 2, and 0 respectively in the previous week. In Northern Ireland the number of measles cases notified declined from 617 to 384; the figures for Belfast were 362, compared with 577 in the previous week. There were 20 deaths in Belfast, scattered over the majority of the urban districts. During the week there were 2 deaths from measles in Dublin.

Corrigenda

In the Registrar-General's weekly return No. 7 certain corrections are made of the figures given in the previous week's returns. For the week ended February 12, 1938, the notifications for England and Wales should read: cerebrospinal fever 33, diphtheria 1,872, dysentery 215, encephalitis lethargica 1, enteric fever 71, ophthalmia neonatorum 101, acute primary and influenzal pneumonia 1,129, acute polio-encephalitis 1, acute poliomyelitis 6, puerperal fever 6, puerperal pyrexia 204, relapsing fever 1, scarlet fever 2,426.

The seventeenth meeting of the well-known society entitled Les Journées Médicales de Bruxelles will be held from April 16 to 20 in order that on the last day the members of this congress may be able to join in the celebrated Floralies Gantoises. Besides the usual scientific discussions there will be an international exhibition of science and art with special reference to their applications in the practice of medicine, surgery, pharmacy, and public health. The fee for participation has been fixed at 100 francs, and for ladies 50 francs. The programme includes a banquet, a gala, and an equestrian display; special social events are being arranged for ladies. More detailed information may be obtained from the general secretary of the congress, Dr. René Beckers, Rue Belliard 141, Brussels.

Medical News

The eleventh British Congress of Obstetrics and Gynaecology will be held in Edinburgh on April 4, 5, and 6, 1939. All those desirous of reading papers are asked to communicate at an early date with the senior local secretary, Dr. E. Chalmers Fahmy, 7, Chester Street, Edinburgh, 3.

Lord Horder will deliver an address on "Human Reactions to Noise" at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on Tuesday, March 8, at 5.30 p.m.

Professor John MacMurray will deliver a lecture on "A Philosopher's View of Modern Psychology" at the next meeting of the Medical Society of Individual Psychology at 11, Chandos Street, W., on Thursday, March 10, at 8.15 p.m. Visitors are welcome.

Mr. F. W. Gamble will deliver the Harrison Memorial Lecture on "Facing Realities" before the Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, W.C., on Tuesday, March 8, at 8.30 p.m., and will receive the Harrison Medal which is awarded biennially to commemorate Colonel E. F. Harrison, a distinguished analytical chemist who was appointed Director of Chemical Warfare in 1918. Colonel Harrison conducted, on behalf of the *British Medical Journal*, the analyses of a number of secret remedies, the results of which were published in these columns at intervals from 1934 to 1912. The analyses were later reprinted by the British Medical Association in book form under the titles of *Secret Remedies* (1909) and *More Secret Remedies* (1912). Both volumes have been out of print for some years.

A symposium on "Industrial Disease," arranged by the London Jewish Hospital Medical Society, will take place at the London Jewish Hospital, Stepney, Green, E., on Thursday, March 10, and will be opened by Dr. H. B. Morgan, Mr. D. C. Norris, and Mr. J. L. Smyth. The president, Professor Samson Wright, will take the chair. Tea will be served at 3.15 p.m.

An address entitled "The Doctor in the Home" will be given to senior students of the twelve medical schools in London and to those who have qualified in the last two years by Sir Kaye Le Fleming, M.D., Chairman of Council of the British Medical Association, on Tuesday, March 8, at 5.30 p.m., in the Great Hall of B.M.A. House, Tavistock Square, W.C. Tea in the Members' Lounge from 5 to 5.25 p.m. A film illustrating the work of the Association will be exhibited at 5.15 p.m., and after the address there will be a "talkie" film dealing with physical fitness education, a subject to which Sir Kaye will allude.

The next meeting of the German Pharmacological Society will be held in Berlin from April 23 to 28 under the presidency of Professor Flury of Würzburg. The subjects for discussion are local anaesthesia, cancerogenic substances, coffee and caffeine. Further information can be obtained from the Pharmakologisches Institut, Dorotheenstrasse 48, Berlin, N.W.7.

A sessional meeting of the Royal Sanitary Institute will be held at Hereford Town Hall on Friday, March 11, at 5 p.m., when discussions will take place on "Changing Values in Public Health Administration," to be opened by Dr. A. Middleton Brown, and on "Some Problems of Rural Housing," to be opened by Mr. H. F. Long.

A meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health will be held at 1, Thornhaugh Street, Russell Square, W.C., on Friday, March 18, at 8.30 p.m., when Dr. J. E. Wilson will read a paper on "How to Breathe." The Fever Hospital Medical Service Group of the Society will meet at 1, Thornhaugh Street, W.C., on Friday, March 25, at 4 p.m., when Dr. V. D. Allison and Dr. R. Cruickshank will open a discussion on "The Spread of Streptococcal Infections as Ascertained by Type Determinations."

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended February 19, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in Eire. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)	
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)	(a)	(b)

(i) 122 great towns in 1937.
(ii) 12 " " " "
(iii) 9 " " " "

* 362 cases in Belfast alone.
† After October 1, 1937, puerperal fever was made notifiable only in the Administrative County of London.

‡ Deaths from puerperal sepsis.
§ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

179 Pleural Exudate following Artificial Pneumothorax

B. PAPANIKOLAU (*Z. Tuberk.*, 1937, 78, 1-2, 7) states that pleural exudate is present in 60 per cent. of cases of artificial pneumothorax and is its most common complication. It is more often seen in incomplete pneumothorax, following fatigue, after infection of the respiratory passages, or where the patient's living conditions are unhygienic. It is rare for a pleural exudate to occur a year or more after the production of an artificial pneumothorax. The exudate is always tuberculous in origin. There is a definite relationship between the clinical manifestations and the manometric pressure: when the latter is positive the symptoms are acute, but as the pressure becomes negative they lessen in intensity. A pleural exudate may have a bad influence on the general condition of the patient; it may give rise to adhesions between the pulmonary and costal surfaces of the pleura; secondary infection of the exudate may threaten the life of the patient; and the efficiency of the lung may be seriously impaired. In the acute stage the exudate should under no circumstances be removed. The production of a negative pressure improves the clinical manifestations rapidly. If secondary infection occurs endopleural wash-outs and surgical measures are indicated.

180 Thrombo-angiitis Obliterans

E. VERDELLI (*Arch. ital. Anat. Istol. patol.*, 1937, 8, 2, 200) records exhaustive post-mortem investigations in a case of thrombo-angiitis obliterans (Buerger's disease) in a rheumatic male subject, aged 30, a moderate smoker and drinker, who after an initial syndrome of migratory phlebitis had gangrene of both feet successively, disappearance of the radial pulse, and immediately before death acute abdominal symptoms explicable by the recent thrombosis of the superior mesenteric artery found at necropsy. The histological findings confirmed the view that the disease is not due to primary venous thrombosis (Buerger himself in the end abandoned this contention) but is a systemic malady of uncertain causation, characterized by a chronic endovascular inflammation: the intimal thickening is a compensatory adaptation of a non-inflammatory nature. The hypothesis of an acute inflammatory causation has probably arisen from histological examinations confined to amputated members. In Verdelli's patient the vascular lesions were chiefly arterial, the vessels being obstructed or occluded by the proliferated intima and by fibrous tissue in which elastic elements were rare; recanalization was well marked, sclerosis of the media and adventitia was less pronounced, and inflammatory signs in the latter were rare. The vessels chiefly affected were those in the limbs, and the iliac, splenic, mesenteric, and small visceral arteries, including those of the liver; the coronary, pulmonary, and cerebral arteries were little changed. Fibrosis secondary to the vascular lesions was well marked in liver and spleen, and present to some extent in the kidneys and in the pancreas.

181 Hodgkin's Disease

F. HARBITZ (*Tidsskr. norske Laegeforen.*, November 15, p. 1167; December 1, p. 1232; December 15, p. 1279, 1937; and January 1, 1938, p. 13) notes that Hodgkin's disease has figured in the vital statistics of Norway since 1927, and that during the eight-year period 1927 to 1934 the notifications of death from this disease have numbered 152 (eighty males and seventy-two females). Professor Harbitz has performed post-mortem examinations on about

fifty cases, and he has investigated during the eleven-year period 1926 to 1936 a total of 122 cases (sixty male and sixty-two female). If due account be taken of the dwindling number of persons in the higher age groups it would seem that the disease grows somewhat in frequency with increasing age, but it occurs at all ages. It is equally common in rural and urban communities and in different occupations, and in Norway, as well as in Sweden, its incidence does not correspond geographically with that of tuberculosis. Indeed in those parts of Norway in which the incidence of tuberculosis is highest that of Hodgkin's disease is comparatively low. The converse is also true. But Hodgkin's disease shows no very high rate of incidence in any locality or in certain families. Professor Harbitz calculates that the average duration of the disease is between two and three years, although it may last as long as twelve years before terminating fatally. In acute cases the disease may prove fatal in only three to four months. Whether it runs an acute or chronic course it invariably ends in death, although x-ray treatment may prolong life. Though Professor Harbitz is sceptical as to the chances of recovery, spontaneously or after treatment, in well-defined Hodgkin's disease, he wonders if there may not be abortive and ill-defined forms of it which terminate in spontaneous recovery as in the case of tuberculosis. He regards the disease as a chronic infection due to a hitherto unknown virus, and though the disease may occasionally be associated with, and may even activate, tuberculosis, he does not believe they have a common aetiology.

Surgery

182 Post-operative Prostatic Changes

H. A. ZIDE (*Proc. Mayo Clin.*, December 8, 1937, p. 769) draws attention to the statements that have been made about the ultimate effect of prostatic operations on the remaining tissue. In order to ascertain whether an increased possibility of malignancy or an increased degree of infection follows transurethral resection as compared with the enucleation type of operation, he has examined microscopically the tissue removed. This was done in eighty-five cases of benign prostatic hypertrophy in which two or more operations had been performed at intervals of three or more months, with the object of determining the changes that had occurred. In eleven of these cases suprapubic enucleation had been undertaken, and in seventy-four a transurethral resection, nearly always of the cold-punch type using the Braasch-Bumpus resectoscope. There was no evidence of abnormal mitosis or malignancy in the parenchyma of the prostatic tissue removed at the second operation. The tissue obtained was studied in regard to evidence of infection, malignancy, and changes in amount and character of the parenchyma, smooth muscle, and fibrous stroma. The investigations showed that the changes in smooth muscle tissue and fibrous stroma after operation are almost parallel; in 30 per cent. of cases both had increased. A decreased quantity of fibrous stroma was present only after transurethral resections, and may indicate a clearing up of infection after this type of operation. There was no evidence from the number of lymphocytes that prostatitis was more frequent after transurethral resection, but it was found that an increase of lymphocytes occurred in those cases in which the second operation did not take place for six months or longer. The results showed that in the series studied there were no early malignant changes, and malignancy was not seen in any case at the time of the second operation. There was therefore no evidence to suggest that there was an increased tendency to the development of carcinoma following transurethral resection as com-

The result of the contest for the Scottish Universities seat, which became vacant by the death of Mr. Ramsay MacDonald, was as follows: Sir John Anderson (Nat. Govt.), 14,042 votes; Miss Frances Melville (Ind.), 5,618 votes; Professor Dewar Gibb (Scot. Nat.), 5,246; and Sir Peter Chalmers Mitchell (Ind. Prog.), 3,868 votes. The National Government candidate secured a majority of 8,424 votes over the next candidate, as compared with 7,359 at the last election.

A meeting of the Harveian Society of London will be held at 26, Portland Place, W., on Thursday, March 10, at 8.30 p.m., when Sir Arthur Hurst will deliver the Harveian Lecture on "Physical Basis of 'Biliousness,' 'Wind round the Heart,' and Some Other Popular Maladies."

We are asked to remind readers that the International Congress on Rheumatism and Hydrology will be held at Oxford from March 27 to 30, followed by the International Congress on Rheumatic Diseases at Bath from March 31 to April 3. Details were published in the *Journal* of January 8 (p. 84). All inquiries about the Oxford Congress should be addressed to the General Secretary, 109, Kingsway, London, W.C.2, and regarding the Bath Congress to the Joint Honorary Secretary, Dr. G. D. Kersley, 6, The Circus, Bath.

The British Health Resorts Association will hold a conference at Hastings on Saturday, March 19, when the two subjects for discussion will be "Horticulture and the Health Resort" and "The Place of the Health Resort in Surgery—Pre-operative and Post-operative."

The Medical Students Committee of the National Union of Students, in co-operation with the Medical Office of the International Confederation of Students, is arranging a tour to Sweden for British students from April 16 to 28. The cost is £14 15s., and the last day for registration is March 14. In addition to general sightseeing, students will have the opportunity of visiting leading hospitals and clinics in Gothenburg, Stockholm, and Uppsala. Information may be obtained from the National Union of Students, 3, Endsleigh Street, London, W.C.1.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

THE TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

THE TELEGRAPHIC ADDRESSES are
EDITOR OF THE BRITISH MEDICAL JOURNAL, Ailiology
Westcent, London.

SECRETARY, Mediscera Westcent, London.
The address of the B.M.A. Scottish Office is 7, Drumsheugh
Garder (telegrams: Associate, Edinburgh; tele-
phone ... and of the Office of the Irish Free
State ... A. and B.M.A.), 18, Kildare Street,
Dublin (telegrams: Lucinus, Dublin; telephone 62550 Dublin).

QUERIES AND ANSWERS

Treatment of Ascites

Professor RUTHERFORD MORISON, F.R.C.S., writes from St. Boswells-on-Tweed with reference to "Perplexed's" request (February 12, p. 370) for advice concerning a patient with ascites: "It has surprised me that no one has answered his query because his patient, although 70 years of age, is almost certain to be cured by omentopexy." Professor Morison encloses a reprint from the *British Medical Journal* of

January 20, 1912, containing his paper on the "Operative Cure of Ascites due to Liver Cirrhosis," read before the Surgical Section of the Royal Society of Medicine. The first paper by Sir David Drummond and Professor Morison in connexion with the subject appeared in the *British Medical Journal* of September 19, 1896.

Dr. W. SUTHERLAND writes: There is in my practice a woman aged 45, with primary carcinoma of the body of the uterus, on whom I have performed paracentesis one hundred and five times. The abdomen is emptied every twelve days, and thirty pints of fluid are removed. As the patient is able to go about her daily duties after tapping it seems that I may carry my score well into the second century.

Primary Vaccination at the Age of 12

Dr. S. H. DE G. PRITCHARD, in reply to "Chelsea" (February 19, p. 432), writes: In spite of experience of war service, three years' residence in the tropics, and vaccinating candidates for the Navy and such public services as the Post Office, I have not so far come across this particular problem of post-vaccinal encephalitis. I have performed primary vaccination in hundreds of patients over this age, and I have yet to meet any untoward effects. Were I in "Chelsea's" place I should not hesitate to vaccinate my own son. Personally I always use Jenner lymph. With regard to the memorandum by the Ministry of Health, I have always understood that such cases of encephalitis as have arisen have invariably followed vaccination with lymph prepared from some animal other than the calf, and so far I have not seen recorded a single case of this condition following vaccination with calf lymph. I believe that the rabbit is the villain, and as a matter of interest I should like to know if my belief is shared by others.

LETTERS, NOTES, ETC.

"The Evolutionary Theory"

Surgeon Rear-Admiral CHARLES M. BEADNELL (Egham, Surrey) writes: In the *Journal* of February 26 (p. 497) Colonel G. F. Rowcroft states that Haeckel "admitted that many of his illustrations were deliberately faked in order to make them fit the theory (of evolution)." I should like proof of this astounding assertion. It is true that certain intolerant opponents of the theory of evolution accused the great zoologist of having forged his illustrations of foetuses and embryos with the intent of misleading his readers, but it is equally true that the accusation was indignantly refuted, not only by Haeckel himself but by leading biologists of his day, many of whom were disbelievers in the then new theory of evolution. Diagrammatic illustrations never can represent an actuality, but merely help readers towards an understanding of what that actuality is; the venomous charge brought against Haeckel in this respect could with equal logic be levelled against any writer of a scientific work illustrated by diagrams. Haeckel's books popularizing science have sold in thousands, and are still selling, and their author, far from being a "subtle" writer indulging in "numerous fallacies," is a master of the clear exposition of truth. Colonel Rowcroft seems to be somewhat inconsistent when he says that he believes in evolution "in the sense of progress," while denying that man has evolved from a more primitive ancestry. In any case his definition of evolution is not in accord with that of modern science, which regards it as an ever-present flux and reflux between relatively complex and relatively simple states of matter and energy. There can be no progress—that is, no advance towards higher differentiation—in the absence of some antecedent retrogression. Evolution includes both progressive and retrogressive processes; each is a *qua non* complementary to the other. In this sense evolution is not a hypothesis, is not even a theory; it is an established fact. Breeders of animals and plants rely on its principles; in transmuting the elements, physicists demonstrate it in their laboratories, while astronomers see it in the vast laboratories of the suns and nebulae. Whether it be within the crust of the earth, beneath the shell of the egg, or inside the mother's womb, the evidence of the truth of evolution is overwhelming.

Corrigendum

In the *Journal* of February 19 we published at page 420 a letter by Captain Kenneth Lindsay on the "Expulsion of Placenta Praevia in Advance of Foetus." In this letter "on admission to the second hospital at 10 p.m." should have read "on admission to the hospital at 10 p.m."

Radiology

187 Kymographic Study of Kienbock's Phenomenon

THOYER-ROZAT and J. BERNARD (*J. Radiol. Electrol.*, November, 1937, p. 499) have examined by means of kymography the movements of the liquid level in hydro-pneumothorax (Kienbock's phenomenon). Their studies revealed that the mechanism of the movements of the liquid level in the ordinary hydro-pneumothorax differs from that seen following phrenicectomy. In the first case the affected hemithorax contracts transversely during inspiration, and the mediastinum, which is drawn towards the affected side, forces the liquid column to rise, but the two halves of the diaphragm move synchronously. In paralysis of the diaphragm, however, the dome of the diaphragm, which has lost its tone, passively follows the variations of the abdominal pressure, with the result that the fluid level rises in inspiration through a decrease of the vertical diameter of the affected hemithorax.

188 Cerebral Arteriography

H. DAVIES (*Brit. J. Radiol.*, December, 1937, p. 871) describes the technique of cerebral arteriography as carried out at the National Hospital, Queen Square, London, and gives a summary of the different arteriographic appearances in the normal brain and in cases of cerebral tumour or aneurysm. He does not believe that the doses of thorotrast used in cerebral arteriography have a delayed deleterious effect on the body. For the diagnosis of tumours of the temporal lobe and cerebellum, which derive their main blood supply from the basilar trunk, the author's advice is to inject this vessel through the subclavian artery; but as the thorotrast is being injected against the blood stream that part of the artery which is distal to the point of injection is compressed, and this makes the thorotrast flow up the vertebral artery and the basilar trunk. With this technique the branches which supply the cerebellum can be clearly seen.

189 Value of Pitressin

L. W. PAUL and S. R. BEATTY (*Amer. J. Roentgen.*, November, 1937, p. 776) recommend the use of pitressin for the elimination of gas in radiography of the urinary tract and of the gall-bladder. For the examination of the urinary tract one ampoule of pitressin (20 pressor units) was given at 8 a.m. A similar dose was given again at 10 a.m. and the radiographs were taken at 11 a.m. A somewhat different procedure was employed in gall-bladder cases. The films were examined as soon as developed. Cases in which the gall-bladder was obscured by gas were given one ampoule of pitressin subcutaneously and repeated radiographs were taken thirty minutes later. The authors met with no serious reaction from the drug, but most patients experienced abdominal cramps and about one-half had an intestinal evacuation following the injection. A few showed "blanching phenomena." The use of the drug, however, is contraindicated in cases of high blood pressure and in cardiac disease. Contraction of the gall-bladder due to pitressin was usually slight and did not interfere with the radiographic examination.

190 Relief of the Gastric Mucosa

A. E. COLCHER (*Radiology*, November, 1937, p. 615) suggests a new technique for the study of the relief of the gastric mucous membrane: 50 to 100 c.cm. of air are injected into the empty stomach by means of a gastric tube, the amount of air varying according to the size of the stomach. The patient is then given four to six ounces of the standard barium meal. The usual radiosopic and radiographic examinations are carried out in the erect position. In the next stage of the process the author uses an adaptable radiographic couch, with a head-rest and

a shoulder-rest, and foot-straps which are applied over the insteps. This allows the patient to be rocked without discomfort from the erect position down to a Trendelenburg position of not less than 45 degrees. Thus when the patient is in the Trendelenburg position the air displaces the barium at the pylorus and the barium displaces the air at the fundus. In rotating the patient to the Trendelenburg position he is made to remain horizontal for at least fifteen minutes to allow for dilution of gastric secretion and cohesion of the barium to the gastric mucosa. Occasionally there is a normal gas-bubble large enough to allow the examination to be carried out without intubation. The author reports a number of observations made by the use of this method, and he believes that it constitutes an easily applied refinement of radiographic procedure.

191 Oesophageal Changes of Aortic Origin

C. A. VIANA-GIURIA (*Arch. Uruguay. Med.*, November, 1937, p. 551) states that radiological examination of the oesophagus is of value not only because it enables its lesions to be localized and in a large proportion of cases facilitates an aetiological diagnosis, but also because it throws light on extrinsic thoracic processes, especially in the mediastinum. The author accepts the following classification by Chaliier of the varieties of dysphagia due to aortic aneurysm: (1) reflex dysphagia, caused by involvement of the recurrent laryngeal nerves, giving rise to atony or spasm of the oesophagus; (2) dysphagia from inflammation of the mediastinal connective tissue, which spreads secondarily to the walls of the oesophagus; (3) dysphagia from direct compression; (4) dysphagia due to rupture of an aneurysmal sac, with formation of a pseudo-aneurysm. Viana-Giuria also describes under the name of "sitius aortae arcus aortae" a congenital abnormality of the aorta and oesophagus, of which he records an illustrative case.

192 Transvesical and Intravenous Pyelography

A. HERZOG and L. ALT (*Z. Urol.*, 1937, 31, 12, 807) point out that transvesical and intravenous pyelography are not rival but complementary methods in renal diagnosis. They illustrate their statement by describing a case of renal carbuncle under their care. The patient had had pain in the right loin for fourteen days. Her temperature was raised and a leucocytosis was present. Little information was to be obtained from the urine. Transvesical pyelography produced a normal pyelogram. Intravenous pyelography showed that there was present in the kidney a destructive process which was pushing the calices apart but which had not broken into them. The diagnosis, confirmed at operation, of an inflammatory expansive process in the renal parenchyma—namely, carbuncle—was made on the strength of both transvesical and intravenous pyelograms.

193 X-Ray Therapy of Rheumatic Heart Disease

R. L. LEVY and R. GOLDEN (*Amer. J. med. Sci.*, November, 1937, p. 597) describe the results of x-ray therapy after eleven years in forty-eight cases of active rheumatic heart disease. The object was to distribute throughout the cardiac area approximately 60 r, as measured in air, corresponding to about one-tenth of the old erythema dose. Treatments were given at intervals of two weeks for four sittings. A period of one to three months was then allowed to elapse and the series of four irradiations repeated. The number of treatments ranged from three to twenty-five and averaged nine. In general those receiving the larger number of treatments fared best. Of forty-eight patients twelve died within six weeks to seven and a half years after treatment, seven showed temporary improvement, and in two no relief was obtained. Of thirty-six living, twenty-five were benefited by treatment and three obtained no relief; in eight cases x-ray therapy was not considered to have been the cause of recovery.

pared with enucleation of the suprapubic type. It was also seen that the prostatic tissue removed at the second operation resembled closely that obtained at the primary operation.

183 Reconstruction of the External Ear

H. GILLIES (*Rev. Chir. structur.*, October, 1937, p. 169) points out that the difficulty of reconstructing the external ear lies in the provision of an adequate supporting framework. Various methods have been tried, including mechanical supports, grafts of costal cartilage or cartilage from the undeveloped ear, and have proved unsuccessful. Homologous grafts of cartilage were also tried, but it was found that although signs of good repair did appear the recipient's blood vessels would not enter the donor skin, and so the graft sloughed away. A two-stage operation has been carried out with heterologous cartilage from the mother or some other female. From the appropriate ear was taken that part of the cartilage which lies above the external auditory meatus and includes part of the conchal support. In the first operation an incision is made in the donor ear parallel to the margin of the helix on its posterior aspect, and the skin is peeled off the cartilage on both sides. The whole of the cartilaginous block is isolated down to the level of the external auditory meatus, and is then cut across, washed in saline, and kept in a wet saline cloth. The skin incision is sutured, and a mould of the natural ear hollows is constructed to support the skin during healing. The reconstruction of the recipient's ear is carried out in two stages, with a three-months interval between each operation. The technique is fully described and illustrated and the value of using a block cartilage graft is stressed. It is suggested that the method will be technically improved and will become a standard procedure.

184 Tuberculosis of the Abdominal Lymphatic Glands

G. H. COLT and G. N. CLARK (*Surg. Gynec. Obstet.*, December, 1937, p. 771) analyse the results of 269 consecutive operations (239 cases), over a period of ten years, for the removal of abdominal lymphatic glands in young adults. Only twenty-eight of the patients could not be traced or examined. Five deaths were due to the operation, three to strangulation, and two to phthisis. The results were excellent in 148 cases, good in twenty-four, poor in fourteen, and bad in fifteen. There were three ventral hernias and two keloid scars. The risk of causing general or local tuberculosis by the operation appears to be very small. With one possible exception no evidence was found in the abdomen of the portal of infection. The "adhesion threshold" is low, there being evidence that the formation of adhesions is far more frequent than in non-tuberculous subjects. Intraperitoneal saline tends to prevent them. A causal connexion between the atrophic appendix and tuberculosis is considered to be unlikely. Out of ninety-three appendices examined only one might have been considered tuberculous. The formation of a sigmoid band, which is found in about 40 per cent. of the cases, or a Jackson's membrane is considered to be due to the organization of lymph where it collects in a peritoneal watershed; this might occur in the foetus. The rate at which calcification occurs is not known. The diagnosis is based on the special variety of the pain, with remissions, as described by the late W. H. Carson; the cause of this has not been explained. Acidosis independent of vomiting is usual during the acute attack. The association of caseation with intestinal obstruction and the formation of bands and adhesions is instanced. The latter occur in over 25 per cent. of the cases. A second operation is often necessary, but should not be undertaken until at least two years after the first, if possible. Carson's dictum that "these operations may be very difficult and trying" is an understatement for the average surgeon. The disease is preventable, and its natural course is towards calcification and cure.

Therapeutics

185 X-Ray Treatment of Rheumatic Diseases

A. KEMEN (*Fortschr. Ther.*, December 13, 1937, p. 684) regrets that deep x-ray therapy has not been much used in rheumatic diseases, and states that at Aix-la-Chapelle during 1936 536 cases were treated with very good results, immediately and in a "follow-up" examination of 200 cases undertaken four to six months later. The term "rheumatic diseases" includes, as well as inflammatory conditions in or near joints, neuritis, myositis, etc., and degenerative arthroses. In general the results were better in cases in which foci of sepsis had been eliminated. In Bechterew's disease (seventy-seven cases with improvement in sixty-seven) three fields were irradiated (200 to 250 r) at two-day intervals, with a repetition fourteen days later; control radiological examinations showed few if any bony changes, so that the improvement is attributed chiefly to diminution of muscular spasm. In the group labelled "chronic polyarthritis due to focal sepsis" (ninety-six cases, with improvement in eighty-four) cases with ankylosis were excluded; since the condition is thought to be due to absorption of toxins via the perineural lymphatics and the cerebrospinal fluid, with subsequent affection of vegetative nerves, irradiations were given to all the sympathetic ganglia in average doses of one application of 200 to 250 r to each of nine fields. Cure was attained in sixteen out of seventeen cases of cervical or brachial neuromyalgia by two or three direct irradiations of the plexus. Coming to degenerative conditions, Kemen records 109 cases improved out of 132 cases of spondylitis deformans (three or four applications, each of 150 to 200 r) and eighty-two and seventy-three improved in cases of arthritis deformans of the hip and knee respectively; for the hip three fields were employed, with 1,200 to 1,500 r in six sessions at six-day to ten-day intervals, and for the knee four fields, with a total dosage of 600 r. In the spine and hip early cases are found unsuitable for x-ray therapy, which gives the best results in cases that are radiologically seen to be of at least moderate severity. The results were especially good in humero-scapular peri-arthritis which had resisted other treatments. In treatment of sciatica irradiations of the lumbar spine (300 to 350 r, repeated after nine days) precede those directed at the nerve trunk.

186 Fatal Atophan Intoxication

N. KNAPPER (*Nederl. Tijdschr. Geneesk.*, January 1, 1938, p. 34), who records an illustrative case, states that in Holland Klinkert in 1926 was the first to draw attention to the dangers of the use of atophan. In the early stage it has an irritating effect upon the liver and may cause a toxic nephritis. In a case recorded by Pinkhof fatal liver atrophy developed after the administration of 27 grammes in the course of six weeks. In one of Tak's cases severe and persistent urticaria set in after taking 2 grammes in three days, and another of his patients after 13 grammes in the course of thirteen days developed dyspepsia followed by jaundice which lasted for six weeks. In America the first fatal case was described in 1925, and up to 1926 200 cases of atophan intoxication have been reported, with eighty-eight deaths. On the other hand, Snijder and his colleagues have treated 2,500 patients with cinchophan (the American name for atophan) in the course of ten years without any damage to the liver, and regard the occurrence of acute yellow atrophy after the use of atophan as a mere coincidence. Knapper's case was that of a woman, aged 60, who after taking 100 mg. of atophan daily for twenty-five days for rheumatoid and gouty symptoms developed acute yellow atrophy, the diagnosis of which was confirmed at necropsy.

THOS. COOK & SON, LTD.,
Berkeley Street, London, W.1.

The authors point out that a just appraisal of the therapeutic benefit of irradiation is difficult owing to the nature of rheumatic heart disease. They believe they have shown, however, that subsidence of carditis appeared in chronic affections soon after the institution of x-ray therapy. Cardiac pain was strikingly relieved in a number of cases. Patients without signs of congestive heart failure and without aortic insufficiency fared best. No harmful results were noted, although unpleasant irradiation reactions occurred in 50 per cent. of cases. The manner in which improvement is initiated is unknown, but it is believed to be due to an altered response of the cardiac tissues induced by the rays. The authors are convinced that x-ray therapy deserves a place in the treatment of properly chosen cases of chronic, early, non-congestive, active carditis of rheumatic origin.

hypogastrium and vaginal haemorrhage, though they were not always associated, as shown by the fact that thirteen patients had pain only. The other symptoms were malaise, vomiting, and collapse, and in thirty-five cases pain in the right shoulder. Painful defaecation was present in seven, and dysuria in twenty-three. No diagnostic value could be attached to the results of examination of the blood or urine. In every case the affected tube was removed, and in fourteen patients the other tube as well, with or without the fundus uteri. Only one death occurred, due to peritonitis following rupture of the tube. In twenty-seven cases the operation was performed on the day of admission, in twenty-four on the day after, in nineteen within a week, and in eleven more than a week after admission.

Obstetrics and Gynaecology

194

Perineal Cross-section

R. K. HOWAT (*J. Obstet. Gynaec. Brit. Emp.*, December, 1937, p. 1094) describes a simple method of limiting perineal rupture by cross-section of the perineum. When rupture occurs with the head well advanced he advocates a transverse incision $\frac{1}{2}$ in. to $1\frac{1}{2}$ in. in length through the thickness of the perineum, the mid-point at the line of rupture, which will then extend into and be stopped by the cut. The incision, which is approximately one inch anterior to the distended anal margin and lies parallel to the transverse perinei and almost tangential to the anal and vaginal sphincters, falls short of the levatores ani as they are forced apart by the biparietal diameter of the head. In comparison with episiotomy, Howat claims an advantage for perineal cross-section, for no incision need be made until rupture has occurred, this rupture is not extended but is checked by delivery, as in episiotomy, and there is no division of muscle.

195 Follicular Hormone in Kraurosis Vulvae

E. TSCHERNE (*Zbl. Gynäk.*, January 15, 1938, p. 169) has investigated histologically the affected skin in a case of kraurosis vulvae before and after treating the vulva with oestroglandol, an ointment each gramme of which contains 1,000 units of crystallized oestrin. A 20-gramme tube of ointment was used up during the course of treatment. The ointment was rubbed into the vulva once or twice daily for three weeks. By the end of that time all the ulcerated areas were cicatrized and the itching had completely disappeared. Histological examination showed a remarkable improvement in the condition of the skin and an absence of inflammatory changes.

196

Tubal Pregnancy

A. J. M. DUYZINGS (*Nederl. Tijdschr. Geneesk.*, December 25, 1937, p. 6128) records his observations on eighty-one cases of tubal pregnancy treated in the obstetrical department of the Royal Hague Hospital from 1930 to 1935. In twenty-four the ovum was implanted in the isthmus and in fifty-five in the ampulla, while in two the situation was unknown. As regards the ages of the patients, seven were between 20 and 24, seventeen between 25 and 29, twenty-five between 30 and 34, twenty-six between 35 and 39, four between 40 and 44, and one between 45 and 49; in one the age was not known. Sixteen were primiparae; in fifteen it was the second pregnancy, in ten the third, in eight the fourth, in twenty from the fifth to the ninth pregnancy, four had had ten or more pregnancies, and in eight the parity was unknown. No fewer than four patients showed evidence of an old haematosalpinx at the operation. In three of these patients the repetition of the tubal pregnancy occurred without a normal pregnancy having intervened. The chief symptoms were pain in the

197 Reticulocyte Count in Lactating Mothers

S. SHIRAISHI (*Tohoku J. exp. Med.*, October, 1937, p. 510) has studied the number of reticulocytes and their distribution according to Heilmeyer's groups in 210 apparently healthy lactating women, whose milk gave positive (normally healthy), weakly positive, or negative (state of avitaminosis B) Arakawa reactions. In twenty-five women whose milk gave normally or strongly positive Arakawa reactions the mean reticulocyte count was 4 per 1,000 of erythrocytes, and the distribution was that seen in normal healthy persons, Type III being the commonest, while cells of Types O and I were not seen. In the weakly Arakawa-positive group (sixty-five women) the mean count was 8 per 1,000, the Type III cells were still the commonest, but cells of Type I were found. In the Arakawa-negative group (120 women) the mean count was 11.4 per 1,000 erythrocytes, none being below 5 per 1,000 erythrocytes; cells of Type II were commonest and cells of Type I were more frequent. Thus the increase was mainly due to an increase in the reticulocytes of Types I and II. The author concludes that mothers secreting milk negative to Arakawa's reaction show an increased reticulocyte count due to an increase of young reticulocytes, probably an early sign of avitaminosis B.

198 Experimental Hyperplasia of the Endometrium

A. LIPSCHÜTZ (*Gynéc. et Obstét.*, November, 1937, p. 403) discusses at length the changes in animals caused by complete ablation of one ovary and almost complete ablation of the other. In the rat and the guinea-pig the microscopical appearance of the endometrium corresponds to that of cystic hyperplasia in women. The proliferation of the uterine glands is remarkable. The mucosa is filled with glandular cavities of different diameters which may form true cysts; the epithelium of the endometrium is hypertrophied; and the cysts are lined with flattened epithelium. In the cavities are desquamated cells and leucocytes. The tunica propria, in which the glands proliferate, also increases. The vessels are dilated and there is extravasated blood around them. Pigment is found just beneath the endometrial epithelium. The uterine cavity is almost always dilated. It is probable that this cystic hyperplasia of the endometrium is due to the persistence of the follicular phase of the ovary; the keratinization of the vaginal cells and the great thickness of the keratinized layer are evidence in favour of this theory. The vaginal mucosa resembles that of pregnancy. The changes suggest a mixture of the signs of oestrus and of pseudo-pregnancy. The changes in the sexual organs indicate an irregular interference with the two fundamental ovarian phases—the follicular and the luteinizing. Despite the prolongation of the follicular phase of the ovary from its function rarely becomes monophasic—that is, follicular; generally it remains biphasic as in the normal ovary.

REPORTS AND ANALYSES

MOUSSEC

(MOUSSEC LTD., 175-6, PICCADILLY, W.1)

This is a sparkling wine of the champagne type prepared from imported grape must and fermented in this country by suitable selected champagne yeasts. The treatment of the wine during and after fermentation is the same as carried out in the well-known wine houses in France. When analysed the following results were obtained:—

Alcohol (by volume)	12.0	per cent.
Equivalent to proof spirit	20.65	"
Total extractives	3.93	"
Consisting of—		
Invert sugar	1.97	"
Cane sugar	0.29	"
Fixed acidity (as tartaric acid)	0.51	"
Mineral matter, &c.	1.16	"
Volatile acidity (as acetic acid)	0.06	"

The wine has the appearance, composition, and general properties of an ordinary dry French champagne. It is light and pleasant to the palate, and has an agreeable aroma. The manufacturers would seem to have succeeded in making, in this country, an attractive and wholesome wine closely resembling the imported product.

THE LANCET, JULY 6, 1935

• When convalescents need a *pick-me-up*

Moussec can be recommended with confidence. Moussec is sparkling wine produced from selected champagne grapes, fermented and matured in this country by the authentic champagne process. A special process of refinement gives to Moussec a purity and digestibility specially suited to invalids. It provides the valuable stimulus of champagne at an everyday price. The shilling "baby" bottle, which fills one champagne glass, provides daily Moussec in convenient form and keeps the wine keen and full of life until wanted for use. (Other bottlings up to 6/6).

The SALTAIR ARTIFICIAL BREAST

RESTORES POISE and CONFIDENCE

● The restoration of the normal line of the bust, after amputation of the breast, has as its happy sequel the restoration of poise and self-confidence. This can be effected by the adoption of THE SALTAIR ARTIFICIAL BREAST, a surgical fitment that is very resilient, has a beautifully smooth surface, and weighs only two ounces. In the special Saltair Brassière it cannot slip out of position. The breast is practically non-absorbent and is easily dried, so that bathing can be indulged in without fear. The breast can be supplied separately for sewing into the patient's own foundation garment if preferred. Further and fuller details will be sent to interested Practitioners upon request.

For support of the lower
abdomen -

panties
designed by J. Roussel

The modern garment for health and beauty

Women will always seek beauty of figure. In the Panties designed by Roussel they have a garment that gives a fashionable line, and one that their medical adviser can approve. Roussel Panties are woven to give support to the lower abdomen, without dangerous pressure on the abdominal organs. Being woven to measure, they do not restrict thighs or waist. The special elastic tricot from which they are woven exerts a gentle massaging action which stimulates circulation, assists in dispersing fat, and encourages the natural eliminative functions. If you would like to know more about Roussel Panties and other figure-control creations designed by Roussel, please phone or write for a copy of our beautifully illustrated Catalogue. Prices from 2 Guineas. A reduction of 2s. in the £ is made on purchases for personal use by members of the Medical Profession. Write to Dept. ME.

De KUYPER'S HOLLANDS

Distilled with the Juniper berry from genuine malt liquor. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from all irritating properties.

It can be described as carminative, anti-spasmodic and a stimulating diuretic, valuable in many conditions and can be safely taken with regularity.

Distilled by the same family for 241 years.

RENAL DYSFUNCTION

and arthritic conditions show marked reaction to treatment with "Adrax" Brand Tablets. Made to a dual formula, the tablets (white and brown) contain well-tried medicaments in an association not generally available. They have a specific effect on the kidneys and bladder, the cathartic element promoting ecrrisis and the complementary alkaline compound restoring the disturbed acid-base equilibrium. There is evidence that pathological manifestations tend to disappear under treatment with Adrax Tablets, and a condition of healthy, normal tonicity is restored to the kidneys, inducing a positive state of increased vigour and all-round health.

ADRAX BRAND TABLETS

Indicated in Nephritis, Cystitis, Prostatitis, Arthritis, Functional Albuminuria, in conditions characterized by retention or suppression of the urine, undue frequency of micturition, or excess of uric acid.

ALASIL

Better Salicylate Therapy

WHATEVER be the season of the year, there is a wide sphere of utility for "Alasil," the improved form of salicylate medication.

"Alasil" is a very definite advance on ordinary compounds of salicylic or acetyl-salicylic acid both in therapeutic efficiency and in freedom from the risk of unpleasant gastro-intestinal sequelae. This high tolerability is due to the fact that "Alasil" is composed of calcium acetyl-salicylate—the least irritating of the salicylate compounds—and "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid.

A careful series of experimental tests has shown that "Alasil" is more completely absorbed than ordinary salicylate compounds and that it is practically free from the risk of liberating free salicylic acid in the stomach.

Wide clinical experience anticipated these findings by demonstrating that "Alasil" can be pushed or prolonged to a much greater extent than ordinary salicylate compounds and that it can be given with safety to children, adults, the aged, and patients with finely-balanced digestive capacities. An analgesic, antipyretic, and sedative of established value.

A supply for clinical trial with full descriptive literature sent free on request.

STEADILY FINDING FAVOUR

MAW STEROTHERM

HOT AIR ELECTRIC AUTOMATIC STERILIZER

Patent No. 427581

Maw Sterotherm Automatic Sterilizers have been installed in the London, Westminster and many other Hospitals, Surgeries, etc., throughout the country and are functioning with the utmost efficiency. The special features of the Sterotherm ensure complete sterilization of Instruments, Dressings, Oils, etc., by the Hot Air method. It is the ideal unit where economy of space and outlay are essential.

May we send you details or arrange a demonstration?

SPECIAL FEATURES

- Efficient Sterilization.
- Automatic regulation of temperature.
- No supervision necessary while in use.
- Very small current consumption.
- Articles in apparatus remain sterile until required, as closure is bacteria-proof.
- Dressings quite dry after leaving Sterilizer.
- Convenient size—length 16½ in., diameter 9½ in.

AN IMPROVED *May* Ophthalmoscope

WITH
ILLUMINATED
AND
MAGNIFIED
NUMBERS

At only slightly increased cost the Gowlland Ophthalmoscope can now be supplied having illuminated and magnified numbers. These are magnified to nearly twice the size of the older pattern and positioned well away from the sight hole; they are brilliantly illuminated, can be read easily in the brightest surroundings and cannot possibly interfere with the observation. The illumination of the numbers is effected by the ordinary Ophthalmoscope Lamp and there is no additional load on the battery.

The patch of light projected by this instrument is bright, circular and absolutely homogeneous, making close examination easier. The reflecting prism is adjusted so that there are no shadows on the fundus, and corneal glare is reduced to the lowest possible amount. The focussing system (Patent No. 358766) and movements are exceptionally smooth in use.

Do you like being lazy ?

Most of us seem to prefer our tobacco READY RUBBED—it saves trouble. That's why we now pack even single ounces of the Ready Rubbed in airtight tins—as shown. But if you prefer your tobacco left in the Original form, you can always get it—in ounce packets. Both cost the same—a convenient shilling an ounce. And if you like to buy a couple of ounces at a time, you can get either sort in the special vacuum tins. Anyway, just try this Cut Golden Bar—it's stood the test of 40 years.

Here's a Delicious Field-Fresh Fruit Juice from Hawaii—YOU CAN RECOMMEND WITH CONFIDENCE TO YOUR PATIENTS

PATIENTS are usually finicky about their diet. They like variety. And Dole Hawaiian Pineapple Juice is a delicious, pure, unsweetened fruit juice which makes a bright and cheerful change in your patients' menu.

Dole Pineapple Juice has been submitted to and has received the Seal of Acceptance of the American Medical Association's Committee on Foods.

The exclusive Dole Fast-Seal Vacuum-Packing Process retains those important fresh-fruit constituents which are so valuable to convalescents. Dole Pineapple Juice is a refreshing, natural juice. A natural source of vitamins A, B, and C. And it has such a refreshing, delicious taste and such field-fresh fragrance, that everyone wants more . . . from adults to children.

J. K. Husband & Co., Ltd., 10 Eastcheap, London, E.C.3.

AN ANALYSIS OF DOLE PINEAPPLE JUICE:

Carbohydrates other than sugars (by difference)	0.38

MAT WEAVERS.—In the sleepy little villages of Keel and Napoopoo, on the Island of Hawaii, one can see the native women at their mat weaving. These are seated under a lauhala tree, from whose leaves the mats are woven. To-day there is a revival of this old art, and many beautiful modern articles are being made.

P.S.

If you will write us on your letterhead we shall be glad to send you a free sample tin of Dole Hawaiian Pineapple Juice.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders, Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

-Res. Tel. Address: Bethlem, Beckenham.

Station: Eden Park (Southern Railway).

Telephone: Springfield 1160-L.

President: VISCOUNT WAKEFIELD OF HYTHE, G.C.V.O.

Treasurer: SIR LIONEL FAUDEL-PHILLIPS, BART.

Physician-Superintendent: J. G. PORTER PHILLIPS, M.D., F.R.C.P.

This REGISTERED HOSPITAL is situated at Monks Orchard, in some 250 acres of park, pleasure and farm grounds. Application can be considered on behalf of patients of the educated classes in a presumably curable condition. With a view to early treatment voluntary or uncertified patients are admitted. Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge. The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms. **TREATMENT ON MODERN PRINCIPLES**—Every facility for specialised investigation and treatment is provided in the Lord Wakefield of Hythe Science and Treatment Unit, including RADIOLOGICAL and DENTAL DEPARTMENTS, BIO-CHEMICAL, PATHOLOGICAL and PSYCHOLOGICAL LABORATORIES. The Medical Staff have access to a panel of Consultants in cases which present unusual symptoms requiring specialised investigation and treatment. Under the direction of qualified officers HELIO-THERAPY, HYDRO-THERAPY and ELECTRO-THERAPY are administered in the Physio-Therapy Department. **INSULIN TREATMENT**—For special cases of mental disorder Insulin Treatment is being carried out with good results and suitable cases are accepted. **OCCUPATIONAL THERAPY**, in the form of various Arts and Crafts, is actively encouraged from the medical aspect, and under the guidance of a competent instructor this department has proved most effective as a therapeutic factor in all stages of mental illness. The promotion of physical fitness is a prominent item of treatment, and this is enhanced by arrangements for patients to take part in Outdoor and Indoor Sports and Entertainments, and special attention is drawn to the physical drill and dancing classes which form part of the regular hospital routine. Application should be made to the PHYSICIAN-SUPERINTENDENT.

NEW LODGE CLINIC, WINDSOR FOREST

This Clinic was founded in 1921 in order to provide for the scientific investigation and treatment of disease by a "team" of physicians and specialists.

All forms of non-infectious medical cases are admitted, special attention being paid to disorders of digestion and metabolism, arthritis, anaemias, asthma, heart and kidney disease, and functional and organic nervous disorders.

Particulars can be obtained on application to the Secretary, New Lodge Clinic, Windsor Forest, Berks.

Telephone: 181 and 182 Winkfield Row.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

OVER TWELVE THOUSAND POUNDS

worth of new equipment, furniture,
service re-organisation have gone into

The CLINIC

during the past two years

YET CHARGES REMAIN THE SAME

TO-DAY The Clinic, the wonderful Nursing Home in Devonshire Place, W. 1, might have been richer by over twelve thousand pounds compared with two years ago—to such an extent have the Public and the Medical Profession responded to its offer of the finest possible Nursing Home Service.

Yet actually it is the Public and the Medical Profession who are the richer—for the whole of that sum (more than £12,000) has, true to the principles embodied in the Constitution of the operating Company, been put back into The Clinic and spent on renewals and improvements of equipment and services; and this without any increase of charges to the public.

A large proportion of the money was spent in a thorough re-organisation of the nursing and catering services, previously at a remarkably high standard. As to catering at The Clinic now: "It seems, nowadays, you have to be ill," wrote a patient there recently, "to learn how to live really well."

While the average charge for a room at The Clinic remains at fourteen guineas, charges actually range, as before, from 10 to 18 guineas, while there are a few suites at 25 to 42 guineas. All these rates include a free dispensary service—an "extra" which cost The Clinic nearly £2,400 last year. Enquiries and visits from the medical profession are welcome, and the Secretary will be glad to furnish further details.

The CLINIC

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

INCORPORATING THE ROSS INSTITUTE.

POSTS OVERSEAS FOR MEDICAL MEN

A register is kept in the School of medical men who are prepared to be considered for posts overseas, and the School is frequently asked to advise plantation and mining companies when such posts fall vacant.

The salaries offered are attractive; conditions of service are governed by standardised forms of contract; and many of the posts offer to medical men a most interesting field in which to practise their profession.

It is desirable that candidates for posts overseas should hold a diploma in tropical medicine and hygiene. The course provided by the London School for the Conjoint Board's Diploma lasts six months and the tuition fee is £40. The course may be taken from October to March or from January to June. There are generally more vacancies in the course commencing in January.

The Director of the Ross Institute is always glad to interview medical men who would like information regarding the possibilities of a career overseas if they will be good enough to make an appointment to call on him. Enquiries may be addressed to

SIR MALCOLM WATSON, Director,
Ross Institute of Tropical Hygiene,
London School of Hygiene & Tropical
Medicine,
KIPPER STREET, GOWER STREET, W.C.1.

THE ROYAL SOCIETY

MOSELEY RESEARCH STUDENTSHIP.

Applications are invited by the Council of the Royal Society for a MOSELEY RESEARCH STUDENTSHIP of the value of £30 per annum awarded for "the furtherance of experimental research in pathology, physics and chemistry, or other branches of science, but not in pure mathematics, astronomy, or any branch of science which aims merely at describing, cataloguing, or systematizing."

Preference will be given on this occasion to applications with reference to research in a Biological subject having some bearing on the problems of pathology.

Applicants should give the names of two referees. Testimonials will not be considered. The subject of the proposed research and the place at which it would be carried out should be given.

The appointment will be for two years in the first instance and may in exceptional cases be renewed from year to year up to a maximum of five years in all.

Applications should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W.1, and should be received as early as possible, in any case not later than May 1st, 1938.

February, 1938

THE ROYAL SOCIETY

FOULERTON RESEARCH FELLOWSHIP.

Applications are invited by the Council of the Royal Society for a FOULERTON RESEARCH FELLOWSHIP IN MEDICAL SCIENCE. Candidates, who must be of British nationality and of pure parentage, should supply the usual personal data and give the names of two referees. Testimonials will not be considered. Applicants and referees at a distance may write direct to the address given below without first obtaining forms. The subject of the proposed research and the place at which it would be carried out should be given.

The appointment will be for two years in the first instance as from October 1st, 1938, and may be renewed annually up to a total of five years. It will be subject to the conditions governing Royal Society Research Appointments. The award will be £100-£200 per annum, with experimental benefits.

Applications should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W.1, and should be received as early as possible, in any case not later than May 1st, 1938.

February, 1938.

EXPERIENCED COACHING IN PHYSIOLOGY, Pathology, and Microscopy. M.D. (Lond.), M.R.C.P.(Lond.), B.S., F.R.C.S. (Lond.). All exams. Clinical Pathology. 7202, B.M.A. House, Tavistock Square, W.C.1.

INDIAN MEDICAL SERVICE

RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or of £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 32 years of age and who are registered under the Medical Acts in Force in Great Britain and Northern Ireland are eligible to apply

CAREERS.

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, specialist and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes: to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

Note.—(1) The rupee is at present stabilized at a rate equivalent to 1s. 6d.

(2) An officer promoted to the rank of Lieut.-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1200 per mensem (basic) plus £40 per month overseas pay.

Extras.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side, which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized hospitals may

be seconded in those posts for a period. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to 18 months.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America and Canada, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pensions are as follows:—

After 17 years' service for pension ..	Per annum.
" 18 ..	£372 0s.
" 19 ..	£403 0s.
" 20 ..	£423 0s.
" 21 ..	£465 0s.
" 22 ..	£502 0s.
" 23 ..	£539 10s.
" 24 ..	£576 10s.
" 25 ..	£614 0s.
" 26 ..	£651 0s.
" 27 ..	£697 10s.
" 28 ..	£744 0s.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months, prior to their embarkation for India on first appointment. Information as to the rates of pay admissible during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the UNDER-SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1. The Selection Committee will meet at the India Office early in April next, and the selected candidates, unless seconded for hospital appointments, will be required to join a course of instruction commencing about 1st May, prior to sailing for India in September, 1938. Applications should reach the India Office as soon as possible.

ROYAL ARMY MEDICAL CORPS

Applications are invited from medical men for appointment to commissions in the Royal Army Medical Corps.

Candidates will, for the present, be selected for commissions without competitive examination, and will be required to present themselves in London for physical examination and interview on, or about, 22nd April, 1938. They must be registered under the Medical Acts, and normally must not be over the age of 28 years.

Successful candidates will, in the first instance, be given short service commissions for five years. During the 4th year of this period they will be given the opportunity of applying for permanent commissions in either the Royal Army Medical Corps or the Indian Medical Service. Those not selected will retire on completion of five years' service with a gratuity of £1,000.

Candidates who are successful will, unless they are seconded to complete a hospital appointment, assemble at the Royal Army Medical College, London, on 2nd May, 1938.

Particulars of the Conditions of Service in the Royal Army Medical Corps, pay and allowances, and forms of application, may be obtained on application, either in writing, or personally, to the Assistant Director General, Army Medical Services, The War Office, London, S.W. 1.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

During 1938, the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa and Malaya.

QUALIFICATIONS.—Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY.—Initial salaries vary from £600 to £700, and rise by increments to a maximum of between £1,000 and £1,200.

PRIVATE PRACTICE.—Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS.—In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES.—Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.

TERMS OF APPOINTMENT.—The appointments are pensionable, subject to a probationary period which varies from two to three years.

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE.—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas.

DUTIES.—Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery, in public health, and in medical research.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S.W. 1.

COUNTY COUNCIL OF MIDDLESEX APPOINTMENT OF OBSTETRIC SURGEONS

Applications are invited from registered Medical Practitioners for the following appointments on the pensionable staff. The appointments are senior ones in the Council's general hospital service, and applicants are expected to be medical men or women of high qualifications and professional attainments who have devoted their time wholly or chiefly to the practice of obstetrics and gynaecology. The successful candidate will work under the direction of the Medical Superintendent of the respective hospital, and the whole of their time must be given to their official duties. They must be prepared to undertake the teaching of students, if required, and to carry out such other duties as the County Council may from time to time direct.

REDHILL COUNTY HOSPITAL. Edware.

SENIOR OBSTETRIC SURGEON

Salary £850 per annum, rising by annual increments of £50 to £1,350 per annum, together with a non-resident cash allowance of £150 per annum in lieu of emoluments.

NORTH MIDDLESEX COUNTY HOSPITAL. Silver Street, Edmonton, N.18.

OBSTETRIC SURGEON

Salary £500 per annum, rising by annual increments of £50 to £750 per annum, and after eight years' service, by two further increments of £50 to £850 per annum, together with a non-resident cash allowance of £150 per annum in lieu of emoluments.

The successful candidates will be required to reside within a short distance of the hospitals to which they are appointed. In the case of an unmarried officer, if accommodation is available, full residential emoluments may be provided in lieu of the non-resident allowance.

The above salaries are inclusive, and any fees received by the officers appointed must be paid over to the County Council.

The appointments, which will be subject to medical examination, will be held during the pleasure of the Council, and are terminable by three months' notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 19th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Obstetric Surgeon."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z,"
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1.
February 28th, 1938.

COUNTY COUNCIL OF MIDDLESEX. TUBERCULOSIS MEDICAL OFFICER.

Applications are invited for the above appointment on the pensionable staff. Salary £750 per annum, rising by annual increments of £50 to £1,000, together with out-of-pocket travelling expenses.

Candidates must be registered Medical Practitioners who have held resident appointment in a general hospital for at least six months, and have had special practical experience in the diagnosis and treatment of tuberculosis in sanatoria or otherwise.

The officer appointed will be required to devote his whole time to his official duties, to work under the administrative control of the County Medical Officer of Health, and to reside in such district as may be required.

The duties will include the charge of tuberculosis dispensaries, the general arrangement for the treatment of tuberculosis patients otherwise than in sanatoria, and such other duties as the Council may direct.

The appointment, which will be subject to medical examination, will be held during the pleasure of the Council and is terminable by three months' notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 19th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Tuberculosis Officer." Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z,"
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1.
February 25th, 1938.

COUNTY COUNCIL OF MIDDLESEX. ANAESTHETIST.

WEST MIDDLESEX COUNTY HOSPITAL. Isleworth.

Applications are invited from registered Medical Practitioners for the above appointment. Candidates must have held resident appointments in a general hospital, and must be specially skilled and experienced in the administration of anaesthetics by modern methods. The officer appointed will be required to administer anaesthetics, and to carry out such other duties as may be allotted to him.

Salary £400 per annum, rising by annual increments of £25 to £475 per annum. The successful candidate will be required to reside within a short distance of the hospital, and will be paid a cash allowance of £100 per annum in lieu of residential emoluments.

The appointment (which will be subject to medical examination, will be held during the pleasure of the Council, and will be terminable by one month's notice on either side) is for a period of four years, at the end of which period the officer will leave the Council's service. In special cases the Council may decide to retain an officer on the established staff, in which case the salary will be increased to £500 per annum, which will be the maximum for a non-resident officer in this grade.

The officer appointed will work under the control of the Medical Superintendent, will devote the whole of his time to official duties, and will have no rights under the Council's superannuation scheme.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 19th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Resident Anaesthetist, West Middlesex County Hospital."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z,"
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1.
February 25th, 1938.

N.B.—The West Middlesex County Hospital is a General Hospital with accommodation for approximately 500 acute and 600 non-acute cases.

COUNTY COUNCIL OF MIDDLESEX

Applications are invited for the appointment of RESIDENT ASSISTANT MEDICAL OFFICER at WEST MIDDLESEX COUNTY HOSPITAL, ISLEWORTH. Candidates must be registered medical practitioners who have held resident appointments in a general hospital.

The officer appointed will work under the direction of the Medical Superintendent and will devote the whole of his time to his official duties.

Salary £400 per annum, rising by annual increments of £25 to £475 per annum with board, lodging and laundry.

The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and is terminable by one month's notice on either side.

The appointment, which does not at present carry any superannuation rights, is for a period of four years, at the end of which period the officer will leave the Council's service. In a special case the Council may decide to retain an officer on the established staff, in which case the salary will be increased to a maximum of £500 per annum.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 19th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Assistant Medical Officer, West Middlesex County Hospital."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z,"
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1.
February 25th, 1938.

PUBLIC HEALTH DEPARTMENT. CITY OF CHESTER. CITY HOSPITAL.

JUNIOR RESIDENT MEDICAL OFFICER required for the above general hospital. Salary £200 per annum, with full residential emoluments. The appointment will be for one year.

Applications, stating age, qualifications and previous experience, together with copies of three recent testimonials, should be sent to the Medical Officer of Health, Town Hall, Chester, by March 20th, 1938.

J. H. DICKSON,
Town Clerk.

COUNTY COUNCIL OF MIDDLESEX. PHYSICIAN.

Applications are invited from registered medical practitioners for the pensionable appointment of Physician to the COUNTY SANATORIUM, HAREFIELD. Applicants are expected to hold high qualifications, and to have devoted themselves wholly or chiefly to the practice of clinical medicine, with special experience in the treatment of pulmonary tuberculosis.

The successful candidate will work under the direction of the Medical Superintendent, and the whole of his time must be given to his official duties. He must be prepared to act as consultant to general medical practitioners outside the sanatorium if called upon so to do, to undertake the teaching of post-graduate students if required, and to carry out such other duties as the Council may from time to time direct.

The appointment is non-resident, and the successful candidate will be required to reside within a short distance of the sanatorium. The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and is terminable by three months' notice on either side.

Salary £1,000 per annum (including living-out allowance of £150 per annum), rising by annual increments of £50 to £1,500. The salary is inclusive, and any fees received by the officer appointed must be paid over to the Council.

The Harefield County Sanatorium, which accommodates 375 patients (men, women and children), has just been completely rebuilt and embodies many new features in hospital construction.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 19th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Physician, Harefield County Sanatorium."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z,"
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1.
February 25th, 1938.

COUNTY COUNCIL OF MIDDLESEX.

NORTH MIDDLESEX COUNTY HOSPITAL. Edmonton.

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the above appointment. Candidates must be registered Medical Practitioners who have held resident appointments in a General Hospital. The duties of the appointment will be partly clinical and partly general. Salary £250 per annum, with board, lodging and laundry, valued at £100 per annum.

The officer appointed will work under the direction of the Medical Superintendent, and will devote his or her whole time to official duties.

The appointment (which will be subject to medical examination, and is terminable by one month's notice on either side) is for a period of six months in the first instance, and may be extended for an additional six months.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 19th. Relationship to any member or officer of the Council must be disclosed in the application.

Application forms are not provided. Envelopes must be endorsed "Junior Assistant Medical Officer, North Middlesex County Hospital." Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z,"
Clerk of the County Council.

Middlesex Guildhall,
Westminster, S.W.1.
February 25th, 1938.

NORTHAMPTON GENERAL HOSPITAL. (351 Beds.)

There will be the following seven vacancies for Resident Medical Officers:

On March 1st. 1 HOUSE SURGEON to the Ear, Nose and Throat Department.

On April 1st. 1 HOUSE PHYSICIAN, 3 HOUSE SURGEONS, 2 CASUALTY OFFICERS.

Salaries will be at the rate of £150 per annum, with board, residence and laundry. Candidates, who must be duly qualified and registered, must be males, and of British nationality.

The successful candidate will be cleared for a period of six months (House Surgeon to the Ear, Nose and Throat Department 7 months), and will be eligible for re-election for a further period of 6 months.

Applications, stating age, qualifications, etc., with copies of three recent testimonials, must reach the undersigned not later than the first post on Wednesday, March 9th, 1938.

GORDON S. STURDRIDGE, M.B.,
February 14th, 1938. Superintendent.

EXAMINING BOARD IN ENGLAND

BY THE
ROYAL COLLEGE OF PHYSICIANS
OF LONDON
AND THE

HORACE H. REW, Secretary.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

LICENCE IN DENTAL SURGERY.

Notice is hereby given that the **SECOND PROFESSIONAL EXAMINATION** will commence on Friday, March 25th, 1938. Candidates are required to give at least twenty-one days' notice of their intention to present themselves for the Examination to the Director of Examinations, Examination Hall, 8/11, Queen Square, London, W.C.1, from whom all particulars relating thereto may be obtained.

HORACE H. REW,
Director of Examinations.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH.

Applications are invited from qualified Medical Practitioners for a **RESEARCH STUDENTSHIP**. This will be tenable for six months, and may be renewed for a second period of six months.

The Institute comprises the following departments: Anatomy and Embryology, Physiology, Pathology, Chemical Pathology, Clinical Bacteriology, Systematic Bacteriology, and Immunology.

The student, who will receive an honorarium at the rate of £200 per annum, may elect to carry out his researches in any one of these departments and would be required to work under the direction of the head of the department concerned.

Preference will be given to old St. Mary's Students.

For further particulars apply to the Secretary, Institute of Pathology and Research, St. Mary's Hospital, Paddington, W.2 to whom applications must be sent not later than March 14th.

RADIUM BEAM THERAPY RESEARCH,
at the Radium Institute,
1, Riding House Street, London, W.1.

ASSISTANT MEDICAL OFFICER, resident, salary £150. Six months' appointment from March 18th, 1938. Applications, stating age, qualifications and experience, with copies of three recent testimonials, to be sent to the Secretary, Radium Beam Therapy Research, not later than March 7th.

The selected candidate will assist with the working of two five-gramme Radium units, and will have the opportunity of combining post-graduate studies with this appointment.

APPLICATIONS FOR MEDICAL PRACTITIONER.

Applications are invited by the **DISTRICT COUNCIL OF KAROONDA, SOUTH AUSTRALIA**, from duly qualified medical practitioners, who are members of the British Medical Association, for private practice in Karoonda and surrounding district, under a guarantee by the Council of £800 per annum.

Applications, stating age and qualifications, and accompanied by copies of credentials, should be in the hands of the Agent General and Trade Commissioner for South Australia, British Industries House, Marble Arch, London, W.1 (from whom further particulars can be obtained), by March 29th, 1938.

By Order of the Council,
Karoonda, E. R. MIELL,
South Australia District Clerk
January, 1938.

**CITY OF BRADFORD.
SANATORIUM—GRASSINGTON.**

ASSISTANT MEDICAL OFFICER required. Appointment tenable for one year at a salary of £175 per annum, plus board and lodgings.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to the undersigned not later than March 23rd, 1938.

Town Hall, Bradford, N. K. FLEMING.
February 26th, 1938.

**DERBYSHIRE COUNTY COUNCIL
ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.**

Applications are invited for the post of Assistant County Medical Officer of Health. Candidates must possess a qualification in Public Health, have had both practical and administrative experience of the medical inspection of school children, the organization of school clinics and infant welfare centres, and have a sound knowledge of the provisions of the Midwives Acts and the rules of the Central Midwives Board.

The Officer appointed will be required to devote the whole of his time to the duties of the office, and to work under the direction of the County Medical Officer.

The salary will be £700, rising by annual increments of £25 to £800 a year, and the appointment will be subject to the approval of the Minister of Health and the Board of Education.

The appointment will be a designated post under the Local Government and Other Officers' Superannuation Act, and the successful candidate will be required to pass a medical examination.

The appointment will be terminable by three months' notice on either side.

Applications, stating age, qualifications and previous experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 15th, 1938. Application forms are not provided.

County Offices, W. M. ASH,
Derby, County Medical Officer of Health
February 18th, 1938.

**DERBYSHIRE COUNTY COUNCIL.
DREBY HALL ORTHOPAEDIC HOSPITAL.
(147 Beds.)****JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER.**

Applications are invited for the post of Junior Resident Assistant Medical Officer at the above Institution. Preference will be given to candidates who have held resident Hospital appointments, and who are competent anaesthetists. Orthopaedic experience is not essential, but will be considered an additional qualification. Married quarters are not provided.

Salary at the rate of £350 per annum, rising by annual increments of £25 to £450 per annum, with board, residence and laundry.

The successful candidate will devote the whole of his time to the duties of his office.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

Application forms may be obtained from the undersigned, to whom they must be returned, together with copies of not more than three recent testimonials, on or before March 16th, 1938.

New County Offices, W. M. ASH,
Derby, County Medical Officer.
February 15th, 1938.

**COUNTY OF KENT.
VENEREAL DISEASES CLINIC.
CANTERBURY.**

Applications are invited from registered medical practitioners (male), who are duly qualified in accordance with the regulations of the Ministry of Health, for the **PART-TIME** appointment of **MEDICAL OFFICER** of the above-mentioned clinic, which is at the Kent and Canterbury Hospital.

One half-day session will be held each week, and the remuneration will be at the rate of three guineas a session, with an allowance for travelling.

The appointment will be terminable at any time by one month's written notice on either side.

Applications, stating age, qualifications and experience, and accompanied by copies of not more than three recent testimonials, should reach the County Medical Officer of Health, Sessions House, Maidstone, not later than March 17th, 1938.

Sessions House, W. L. PLATTIS,
Maidstone, Clerk of the County Council.
February 26th, 1938.

**CITY OF NORWICH.
ASSISTANT MEDICAL OFFICER OF
HEALTH AND ASSISTANT SCHOOL
MEDICAL OFFICER, etc**

Applications are invited for the post of Assistant Medical Officer of Health and Assistant School Medical Officer, to include the duties of Medical Officer with residence at the Isolation Hospital. Salary £600 per annum (including emoluments, valued at £150 per annum), rising by annual increments of £25 to £700 per annum. Board allowance at the rate of £60 per annum granted when absent from hospital on leave. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922. For particulars apply to the Medical Officer of Health, 63, St. Giles Street, Norwich, by whom applications for the post must be received not later than March 21st.

**CITY OF BIRMINGHAM
COLESHILL HALL****DEPUTY MEDICAL SUPERINTENDENT.**

Coleshill Hall, a colony for Mental Defectives of all ages and both sexes, consists of 12 divisions, five miles apart, situated at Coleshill and Marston Green respectively, each about 100 miles from Birmingham.

Applications are invited for the whole-time appointment of Deputy Medical Superintendent for the Colony, aged 40 to 45, with experience in institutional administration. Salary according to experience (Scale £200-£700 per annum), subject to satisfactory service, plus emoluments consisting of unfurnished house, fuel, light and laundry valued for superannuation purposes at £20 per annum. An additional £50 per annum will be granted if holding a recognized qualification in psychological medicine. All fees, allowances and remunerations received other than the foregoing must be repaid to the City Council.

The candidate appointed will be required to pass satisfactorily a medical examination and to be subject to the provisions of the Asylums Officers' Superannuation Act, 1909, as modified by the Asylums and Certified Institutions (Officers' Pensions) Act, 1918. The appointment will be subject to one month's notice on either side.

Application forms may be obtained from the Medical Superintendent, Coleshill Hall, Coleshill, near Birmingham, and must be returned to him not later than Monday, March 7th, 1938.

Council House, F. H. C. WILTSHEIRE,
Birmingham, 1 Town Clerk

**CITY OF BIRMINGHAM
SEELY OAK HOSPITAL. (520 Beds.)****RESIDENT PHYSICIAN.**

Applications are invited for the above whole-time appointment from fully qualified registered medical practitioners who have had good medical experience, and who should hold the degree of Doctor of Medicine of one of the Universities of the United Kingdom, or who should be members of the Royal College of Physicians of London.

Furnished quarters, rations, laundry and attendance will be provided, or alternatively a cash allowance will be paid if the officer appointed should be non-resident.

Salary will be £650, rising by annual increments of £50 to a maximum of £900 per annum, together with the emoluments stated above.

The appointment will be dependent on the candidate passing a medical examination, and be subject to the Birmingham Corporation's Superannuation Scheme and the Birmingham Municipal Officers' Widows' and Orphans' Pensions Scheme (if applicable). The appointment will be terminable by one month's notice on either side.

Further particulars of the appointment may be obtained from the Medical Superintendent of the Hospital.

Applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, and endorsed "Physician," should be sent to the Medical Superintendent not later than Wednesday, March 23rd, 1938.

The Council House, F. H. C. WILTSHEIRE,

Salary £350 per annum, rising to £400 per annum by annual increments of £25, with board, residence and laundry.

The office has been designated as an extra post under the Local Government and Other Officers' Superannuation Act, 1922.

Applications, stating age, qualifications and experience, with copies of three recent testimonials, to be sent on or before March 15th, 1938, to the Medical Officer of Health, Town Hall, Sheffield.

CITY AND COUNTY OF BRISTOL

ASSISTANT MEDICAL OFFICER OF HEALTH FOR AIR-RAID PRECAUTIONS.

The Corporation of Bristol invite applications for the post of Assistant Medical Officer of Health for Air-raid Precautions.

The gentleman appointed must have received training in Air-raid Precautions and have knowledge of anti-air work. He will be required to devote the whole of his time to his duties and will not be allowed to engage in private practice. He will work under the direction of the Medical Officer of Health.

The appointment will be temporary in the first instance and will be for a period of two months on either side, and the selected candidate will be required to pass a medical examination.

The salary will be £500 to £700 per annum, according to experience.

Applications must be made on a prescribed form, which may be obtained from the undersigned and must be delivered to the Council House, Bristol, not later than March 15th, 1938. Envelopes should be endorsed "Assistant Medical Officer of Health." Canvassing of members of the Council, either directly or indirectly, will be disqualifying.

The Council House, JOSIAH GREEN,
Bristol, Town Clerk.
February, 1938.

COUNTY BOROUGH OF OXFORD

ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER (Male)

Applications are invited for the above post at a salary of £500 per annum, rising by increments of £25 to £700 per annum, plus a motor car allowance in accordance with the scale adopted by the City Council.

Candidates must have had at least three years professional experience and special experience in ante-natal and Maternity and Child Welfare work and in the work of the School Medical Service. The person appointed will be required to devote his full time to the duties and not to engage in private practice.

The duties to be performed will be under the direction of the Medical Officer of Health.

The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to undergo a medical examination.

Forms of application can be obtained from the Medical Officer of Health, Greyfriars, Paradise Street, Oxford, to whom they must be returned completed on or before March 26th, 1938.

Town Hall, Oxford. A. HOLT, Town Clerk

COUNTY BOROUGH OF SMETHWICK.

St. Chad's Hospital, Birmingham

HOUSE SURGEON.

Applications are invited from registered Medical Practitioners for the appointment of House Surgeon at the Council's Municipal Hospital. The appointment will be for a period of six months from April 6th, 1938, with salary at the rate of £150 per annum with the usual emoluments. If the successful candidate is reappointed for a further period of six months, the salary will be at the rate of £200 per annum. St. Chad's Hospital contains 145 beds, and the cases treated include general medical, acute surgical and maternity patients. It is staffed by the Honorary Consultants of the Birmingham teaching hospitals.

Form of application may be obtained from the Medical Superintendent, St. Chad's Hospital, Haxley Road, Birmingham, 16, to whom application, endorsed "House Surgeon" and accompanied by copies of three recent testimonials, must be delivered not later than March 17th, 1938.

Canvassing, directly or indirectly, will disqualify Council House, FRANK CHAPMAN,
Smetwick, Town Clerk.
February 25th, 1938.

COUNTY BOROUGH OF DERBY.

DERBY CITY HOSPITAL.

ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the post of Assistant Resident Medical Officer (male) at the above hospital of 300 beds. This hospital provides treatment for acute medical and surgical cases, obstetrics and children's diseases, etc. Vacancy will occur near the end of April, and applicants should state when they are free to commence duties.

Candidates must be registered in Medicine and Surgery. The appointment is for a period of six months; two months' notice of termination of duties may be given on either side.

Salary at the rate of £200 per annum, with board and residence.

Applications, stating age, experience, and accompanied by three recent testimonials, should be sent to the undersigned as soon as possible.

EDWARD L. WIRGMAN,

House Governor and Secretary.

WARWICKSHIRE COUNTY COUNCIL.

DEPUTY COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications are invited from registered medical practitioners not over 45 years of age holding the Diploma of Public Health for the post of DEPUTY COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER. Previous administrative experience will be considered an advantage.

The salary is at the rate of £750 per annum, rising by annual increments of £50 to a maximum of £950 per annum, and is subject to a deduction of 5 per cent. in respect of contributions under the Local Government and Other Officers' Superannuation Act, 1922.

The person appointed will be required to use his own motor car in the service of the Council and will be paid in respect of such use a mileage allowance in accordance with the Council's scale from time to time in force. Subsistence allowances according to scale will also be paid.

The appointment is subject to the production of a medical certificate in a form satisfactory to the County Medical Officer of Health. Forms of application and statement of the duties and terms of appointment can be obtained from the County Medical Officer of Health, Shire Hall, Warwick, to whom applications with copies of not more than three recent testimonials should be sent not later than Monday, March 28th, 1938.

Canvassing, directly or indirectly, will be a disqualification.

L. EDGAR STEPHENS,
Clerk of the Council.

Shire Hall, Warwick.
February 26th 1938.

NORFOLK COUNTY COUNCIL

ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited from medical practitioners holding a diploma in public health or similar qualification.

The salary will be £600 per annum rising, on satisfactory service, by yearly increments of £25 to £700, with travelling expenses in accordance with the Council's scale. The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the salary will be subject to the statutory deduction for this purpose. The successful applicant will be required to pass a medical examination.

The Officer appointed will act under the County Medical Officer as Medical Officer to the County Isolation Hospital (non-resident) as Assistant School Medical Officer for a small area, Medical Officer to Infant Welfare Centres, and will be required to perform such other duties as may be assigned to him. He will be required to reside at East Dereham.

The appointment will be subject to three months' notice by either side.

Applications must be made on the prescribed form, which can be obtained from the County Medical Officer, Public Health Department, 29, Thorpe Road, Norwich, to whom they should be returned, accompanied by copies of three recent testimonials, not later than March 15th, 1938.

H. C. DAVIES,
County Officer, Clerk of the County Council,
Thorpe Road, Norwich.

NORFOLK COUNTY COUNCIL

APPOINTMENT OF TEMPORARY MEDICAL OFFICER.

Applications are invited from medical practitioners with special experience of mental deficiency in children.

The salary will be at the rate of £600 per annum, with travelling expenses in accordance with the Council's scale, and the appointment is expected to last for about twelve months.

The Officer will be required to act under the County Medical Officer. The duties will be the examination of all dull and backward children in the county, and the completion of the Board of Education Report Form for those who are mentally defective.

The appointment will be subject to one month's notice by either side.

Applications must be made on the prescribed form, which can be obtained from the County Medical Officer, Public Health Department, 29, Thorpe Road, Norwich, to whom they must be returned, accompanied by copies of not more than three recent testimonials, not later than March 15th, 1938.

H. C. DAVIES, Clerk of the County Council,
Thorpe Road, Norwich.

KENT AND CANTERBURY HOSPITAL.

Canterbury.

HOUSE SURGEON (required (male, unmarried). Six months' appointment, commencing end of March 1938. Salary £125 per annum, with board, residence and laundry. The hospital is recognized under F.R.C.S. regulations.

Applications, together with copies of testimonials, should be sent immediately to the undersigned.

J. F. KENT,
Superintendent and Secretary.

SEATON VALLEY URBAN DISTRICT COUNCIL.
WHITLEY AND MONKSEATON URBAN DISTRICT COUNCIL.
LONGBENTON URBAN DISTRICT COUNCIL.
APPOINTMENT OF WHOLE-TIME MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of a Whole-time Medical Officer of Health for the combined area consisting of the above-mentioned Urban Areas, at a commencing salary of £900 per annum, plus car or travelling allowances, in the first instance amounting to £100 per annum. The Medical Officer appointed will be required to furnish to the Joint Committee a record of his mileage and out-of-pocket expenses at the end of each twelve months, when the question of the expenses to be paid during the ensuing year will be considered.

The successful applicant will also be required to serve as Medical Superintendent of the Earsdon Joint Isolation Hospital Board, which Board receives and treats the whole of the infectious diseases occurring within the above area, together with the Boroughs of Blyth and Wallsend. The additional salary to be paid in connexion with the Hospital appointment will be £200 per annum.

The total population of the three combined areas is 76,490; the population of the Hospital District is 153,568.

Applicants must be registered in the Medical Register as a holder of a Diploma in Sanitary Science, Public Health or State Medicine, in addition to the statutory qualifications, and the successful applicant shall be restricted by the terms of his employment from engaging in private practice as a Medical Practitioner.

The successful applicant will be required to submit to the Ministry of Health and the County Council the appropriate information required under the Local Government Act, 1933, and the Sanitary Officers' (Outside London) Regulations, 1935, report to and attend the appropriate Committees of the above authorities, perform the duties imposed on a Medical Officer of Health by statute and by any orders, regulations or directions from time to time made or given by the Minister and any By-laws or instructions of the Local Authorities applicable to his office.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the passing of a medical examination.

The appointment will commence on the first day of August, 1938, and may be determined by the Medical Officer of Health appointed by three months' notice.

The successful applicant will be required to reside in the area above mentioned.

Applications, stating age and qualifications, together with copies of not more than three recent testimonials, to be sent in to the undersigned by first post on Saturday, March 19th, 1938.

Dated this 11th day of February, 1938.
 Council Offices **ARTHUR S. RUDDOCK,**
 Whitley Bay. Clerk to the Joint Committee.

LANCASHIRE COUNTY COUNCIL.

PARK HOSPITAL, DAVYHULME,
 near MANCHESTER.

APPOINTMENT OF SECOND RESIDENT MEDICAL OFFICER.

Applications are invited from registered Male Medical Practitioners for the appointment of Second Resident Medical Officer at the above Hospital. Candidates must be unmarried.

Candidates must have had previous hospital experience, and preference will be given to candidates who have had experience in diseases of the ear, nose and throat, and children's diseases.

Salary £300 per annum, together with usual residential allowances.

The appointment will, in the first instance, be for a period of six months, the successful applicant being eligible for reappointment for a further period of six months at the end of that period.

The Hospital comprises 500 beds for acute cases, is fully equipped in every respect, and is recognized as a complete Training School for Nurses.

The appointment will be terminable by one month's notice on either side.

Forms of application may be obtained from the County Medical Officer of Health, Hospital and Medical Department, County Offices, Preston, to whom all applications, accompanied by copies of not more than two recent testimonials, must be forwarded so as to be received not later than Saturday, March 12th, 1938.

GEORGE ETHERTON,
 Clerk of the County Council.

County Offices, Preston.
 February 28th, 1938.

FREE EYE HOSPITAL, SOUTHAMPTON.

The Committee require the services of a duly qualified **HOUSE SURGEON** to enter on duties on April 1st, 1938. Salary £150 per annum, with board, residence and laundry. Post-graduate experience in Ophthalmology is desirable. Applications, with three recent testimonials, to reach the Secretary by March 19th, 1938.

LONDON COUNTY COUNCIL.

Applications invited from MEDICAL PRACTITIONERS of at least one year's standing to undermentioned positions. Experience in a resident appointment in a general hospital for at least six months desirable. Married quarters not available.
ASSISTANT MEDICAL OFFICER (Grade II).
 —Salary £350-£425, with board, lodging and washing.

(a) **ST. LUKES HOSPITAL, LOWESTOFT, SUFFOLK.**—Experience in the treatment of non-pulmonary tuberculosis desirable.

There is no accommodation for a woman officer.
ASSISTANT MEDICAL OFFICER (Grade II).
 —Salary £250 a year, together with board, lodging and washing. Appointment for one year only in first instance (renewable for a second year under certain conditions).

(b) **HIGH WOOD HOSPITAL FOR CHILDREN, BRENTWOOD, ESSEX.**—Experience in children essential and in tuberculosis desirable.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division, 2A, County Hall, S.E.1, returnable by March 14th. Canvassing disqualifies.

THE URBAN DISTRICT COUNCIL OF DAGENHAM.

DEPUTY MEDICAL OFFICER OF HEALTH (Male).

Applications are invited from duly qualified medical men for the post of Deputy Medical Officer of Health. Preference will be given to candidates possessing the Diploma of Public Health or an equivalent qualification.

Commencing salary £600 per annum, rising by annual increments of £25 to £750, subject to superannuation deductions. The gentleman appointed will be required to devote the whole of his time to the duties of the office, which consist mainly of work in the Maternity and Child Welfare Department, but may also include duty in any section of the health services of the district.

Experience in ante-natal and maternity and child welfare work is essential. Opportunities will be available for acquiring experience in Public Health administration.

Application forms and further particulars obtainable from the Medical Officer of Health at the under-mentioned address upon receipt of a stamped addressed foolscap envelope. Closing date, March 14th, 1938. Canvassing disqualifies.

Civic Centre, F. W. ALLEN,
 Dagenham, Essex. Clerk of the Council.
 February 15th, 1938.

THE ROYAL EASTERN COUNTIES' INSTITUTION FOR THE MENTALLY DEFECTIVE, COLCHESTER.

ASSISTANT MEDICAL OFFICER (Male)

Applications are invited for the above post from unmarried male Medical Practitioners, not over 36 years of age. Total beds over 1,700.

The medical man appointed will be stationed at the new Extension, Turner Village, and will be required gradually to assume responsibility for administrative work connected with that extension, which has at present over 400 beds. For that reason the commencing salary has been fixed at £400 per annum, together with furnished apartments, board, laundry and attendance. No deductions. Previous specialization in Mental Deficiency is not essential.

A Research Department, with a Medical Director and other staff, working under the Medical Research Council and the Rockefeller Foundation, is attached to the Institution. New laboratories are completed, and there is every facility for research work.

Apply before March 9th, giving age, nationality, full details of qualifications, and copies of testimonials, to the Medical Superintendent, Royal Institution, Colchester.

EAST SUSSEX COUNTY COUNCIL.

SOUTHLANDS HOSPITAL,
SHOREHAM-BY-SEA.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from fully qualified male registered Medical Practitioners (unmarried) for the post of Assistant Resident Medical Officer at Southlands Hospital, Shoreham-by-Sea, near Brighton. The appointment is for one year. Salary £300 per annum, with board, residence and laundry. The Hospital (350 Beds) is a general hospital, under the administration of the East Sussex County Council. The duties of the post will be mainly concerned with surgical cases (including children) and the administration of anaesthetics, but there are also opportunities for medical and obstetrical experience.

Applications should be made on a form obtainable from the undersigned at the County Hall, Lewes, and must be returned to him by Tuesday, March 8th, 1938.

HUGH J. T. McILVEEN,
 Clerk of the County Council.
 County Hall, Lewes
 February, 1938.

COUNTY OF DORSET.

MEDICAL OFFICER OF HEALTH
 for Shaftesbury Borough, Shaftesbury, Sturminster and Sherborne Rural Districts and Sherborne Urban District and
ASSISTANT COUNTY MEDICAL OFFICER

Applications are invited from medical practitioners not exceeding forty years of age for the joint whole-time appointment of Assistant County Medical Officer and Medical Officer of Health for the Shaftesbury Borough, Shaftesbury, Sturminster and Sherborne Rural Districts and the Sherborne Urban District (population about 31,000). The appointment as Medical Officer of Health will, in the first instance, be in respect of the first three named districts only and in respect of the last two named districts when vacancies occur.

The salary for the combined appointment will be £800 per annum, together with a travelling allowance of £100 per annum, an office allowance of £50 per annum, and necessary out-of-pocket expenses according to the scales now in force.

Applicants must be qualified in accordance with Article 8 of the Sanitary Officers' (Outside London) Regulations, 1935, and hold the Diploma in Public Health or similar qualification.

The candidate appointed will, as regards his duties as Assistant County Medical Officer, come under the direction of the County Medical Officer of Health, and will be required to perform such duties as may be from time to time prescribed. As regards his duties as Medical Officer of Health, he will be subject to the control and direction of the District Councils concerned.

The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. He will also be required to reside within the area for which he is Medical Officer of Health, and to take up his appointment on July 1st, 1938.

Candidates must apply on the prescribed form to be obtained from the undersigned, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than Saturday, March 12th, 1938.

Canvassing in any form will be a disqualification.
C. P. BRUTON,
 Dorchester, Clerk of the County Council.
 February 15th, 1938.

SURREY COUNTY COUNCIL.

ASSISTANT MEDICAL OFFICER

Applications are invited for the appointment of an Assistant Medical Officer (Male). Applicants must possess a qualification in Public Health, and should have had experience in the Medical Inspection of School Children and in Maternity and Child Welfare work.

The officer appointed will be required to undertake such other Public Health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County of Surrey, and devote his whole time to the work.

Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health and of the Board of Education, to the successful candidate passing a medical examination, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Staffing Regulations of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Wednesday, March 9th, 1938.

Canvassing, directly or indirectly, will disqualify.
DUDDY AUKLAND,
 County Hall, Clerk of the County Council.
 Kingston-upon-Thames.
 February 21st, 1938.

DEVON MENTAL HOSPITAL

Required, **JUNIOR ASSISTANT MEDICAL OFFICER (male)**, unmarried, who must be fully qualified and registered. Preference will be given to candidates who either have or are about to obtain a Diploma in Psychological Medicine and who have held resident hospital appointments. The Hospital is fully equipped with complete theatre, bacteriological laboratory, etc.

Salary £140 per annum, rising to £175 per annum, with £40 in addition to be paid for board, the D.P.M., and board, apartment, laundry and attendance, valued at £100.

The appointment is subject to the provisions of the Asylums Officers' Superannuation Act, 1920. Form of application to be forwarded to the Clerk of the Devon Mental Hospital, from whom it must be completed and returned not later than March 24th, 1938.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.

Applications are invited for the post of **FOURTH PHYSICIAN** (male) to the Hospital. Candidates must be Graduates in Medicine, Members of the Royal College of Physicians, London, or shall proceed to obtain that Diploma, and must not be engaged in general practice. The successful candidate will have charge of beds and will do two Out-patient Clinics per week, and there is an honorarium of fifty guineas attached to the post.

Applications, with copies of not more than four testimonials, should reach the House Governor not later than March 11th.

Candidates will be required to call upon Members of the Medical Staff, whose names, together with the Standing Orders relating to the post, will be forwarded by the House Governor.

W. H. SIDNELL,

February 21st, 1938. House Governor

Salary at the rate of £100 per annum. Applications should be sent to the Secretary not later than the first post on Friday March 12th, 1938.

February 25th, 1938.

AMENDED ADVERTISEMENT. BOROUGH OF EALING. ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified Medical Men (single) with a Public Health qualification for the position of Assistant Medical Officer.

A candidate must have had experience in the treatment of cases of infectious disease at an Isolation Hospital. The duties will include the medical care of patients in the Chiswick and Ealing Isolation Hospital, South Ealing, and the medical inspection and treatment of school-children at Ealing.

The person appointed will reside at the Isolation Hospital where furnished rooms and board will be provided.

He will be required to devote his whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £450 per annum, rising by £25 per annum to a maximum of £550, plus board and residence, as indicated above and valued at £150 per annum.

A deduction of 5 per cent will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to connection therewith. Canvassing will be a dis-qualification.

Copies of the application forms and terms of appointment can be obtained from Dr. Thomas Orr, Medical Officer of Health, Town Hall, Ealing, W.5, to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than March 17th.

R. H. WANKLYN,
Town Clerk.

GLOUCESTERSHIRE COUNTY COUNCIL. TWO ASSISTANT COUNTY MEDICAL OFFICERS OF HEALTH.

Gloucestershire County Council invite applications for the appointments of Two Assistant County Medical Officers of Health.

The salary in each case will be on the scale £500 p.a. x £25 to £700 p.a., and past local government service will be counted in assessing the commencing salary. Travelling and subsistence allowances will be paid in accordance with the Council's scale.

The posts are designated for the purposes of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidates will be required to pass a medical examination by the Council's medical adviser. Applicants must be registered Medical Practitioners and should hold a Diploma in Public Health. Previous experience in various branches of public health and school medical work is desirable.

Forms of application, with particulars of the duties and conditions of appointment, may be obtained from the County Medical Officer of Health, Shire Hall, Gloucester, to whom completed applications, with copies of three recent testimonials, should be sent not later than March 21st, 1938.

Canvassing, directly or indirectly, will disqualify. RICHARD L. MOON,
Clerk of the County Council
Shire Hall, Gloucester.

APPOINTMENTS.—Contd.

THE PRINCESS BEATRICE HOSPITAL.
Earl's Court, London, S.W.5.
(General Hospital—81 Beds.)

CASUALTY OFFICER AND OBSTETRIC HOUSE SURGEON (male or female) required for a period of six months as from April 1st, 1938. Salary at the rate of £110 per annum, with board, residence and laundry (together with £10 to cover all duties during the six months relating to private patients). Previous resident experience desirable, but not essential.

Full particulars may be obtained from the Secretary-Manager, by whom applications, with copies of three recent testimonials, should be received not later than 9 a.m. Tuesday, March 8th, 1938.

YORK COUNTY HOSPITAL.
(204 Beds.)

Applications are invited for the post of HOUSE SURGEON. Salary £150 per annum, with board, residence and laundry.

Applications, stating age and previous experience, together with copies of not more than three recent testimonials, to be sent to the undersigned not later than 9 a.m. on Monday March 14th, 1938.
J. R. MACKRILL, Secretary.

VICTORIA HOSPITAL, BURNLEY.
(150 Beds.)

HOUSE PHYSICIAN (Male).

Applications are invited for the above post, which will become vacant on March 8th. The duties include the giving of a certain number of anaesthetics. The appointment is for six months in the first instance, at a salary of £150 per annum, together with board, residence and laundry. At the end of this period reappointment may be applied for, and, if granted, the salary for the second six months will be at the rate of £200 per annum. Applications, giving full details of qualifications and experience, stating nationality, together with copies of recent testimonials, should be addressed to the undersigned forthwith.
J. E. WHEATCROFT, Secretary.

THE PRINCESS ELIZABETH OF YORK HOSPITAL FOR CHILDREN.
Shadwell, London, E.1.
(Formerly East London Hospital for Children.)
(135 Beds.)

A HOUSE PHYSICIAN is required on April 1st, 1938, by the above Hospital. Candidates are invited to send in their applications, addressed to the Secretary, not later than the first post on Tuesday, March 8th, 1938, accompanied by copies of not more than three recent testimonials and evidence of having held a responsible hospital appointment. The appointment is for six months. Salary at the rate of £125 per annum, with board, residence and laundry.

Candidates must be properly registered in this country. Forms of application and copies of the rules can be obtained from the Secretary-Superintendent.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST,
Brompton, S.W.3.

The Committee of Management give notice that a vacancy will shortly occur in the office of PHYSICIAN to the Hospital.

Intending applicants, who must be Fellows or Members of the Royal College of Physicians, London, should address applications, accompanied by testimonials, not later than Thursday, March 10th, to the undersigned. The Senior Assistant Physician is a candidate for the appointment.

F. G. ROUVRAY, Secretary.

February 24th, 1938.

WREXHAM AND EAST DENBIGHSHIRE WAR MEMORIAL HOSPITAL.
(129 Beds.)

Two RESIDENT HOUSE SURGEONS required by the above Hospital (male or female), to commence duty on April 1st, 1938. Appointment is for six months. Salary £150 per annum, with board and lodging.

Applications, stating age, nationality, experience and qualifications, to be sent, together with copies of three recent testimonials, to the undersigned immediately.

LESLIE SPENCER, Secretary.

March 1st, 1938.

THE BUCHANAN HOSPITAL.
ST. LEONARDS-ON-SEA.

Practices and Partnerships for Disposal (continued).

26 MIDLANDS.—PRACTICE in good town, easy access to London. Earnings average £2,800. Panel 1,900. Large house with garage and garden. Rent £150 p.a. Vacancy for a physician on staff of local hospital; also scope for surgery and gynaecology. Premium two years' purchase.

27 EAST ANGLIA.—PARTNERSHIP in Practice, over £5,500, in first-rate country town. Panel nearly 1,550. Incoming partner should preferably be graduate of Oxford or Cambridge, and must have had surgical training and ability to do surgical work on county hospital.

28 LONDON, S.E.—PARTNERSHIP in rapidly growing district, 20 minutes from Charing Cross. Receipts average £4,275 p.a. Panel about 3,000. Specially designed modern labour-saving house (4 bedrooms), garage and good garden. Rent £110 p.a. Hospital facilities. Premium one-fourth share £2,250, to include drugs, etc. Possible further share in about 12 months.

29 S.W. ENGLAND.—Ear, Nose and Throat PRACTICE in large town. Cash receipts over £3,000 p.a. Fees £2 2s. 0d. Good house, containing 14 rooms with garage and garden. Price £2,500. Scope. Premium £2,500. Purchaser must be experienced and possess the F.R.C.S. or D.L.O.

30 EASTERN COUNTIES.—PARTNERSHIP in Practice, over £5,000 p.a., in county town. Panel over 5,000. Main surgery premises (4 bedrooms, etc.), garage and garden, to rent. Premium one-fifth share two years' purchase. Further share in seven years. Short Assistantship.

31 HOME COUNTIES.—PARTNERSHIP in sound old-established Practice, averaging about £4,800, in beautifully situated country town. Panel about 2,000. Visits 3/6 to £1 1s. Incoming partner should preferably be a graduate of Oxford or Cambridge, must have held hospital appointments and be experienced in surgery. Excellent hospital. Share worth about £1,000 (or more) at two years' purchase with good prospects of increase.

32 LONDON, S.E.—Old-established PRACTICE in growing suburban district. Receipts average over £1,500 p.a. (appointments worth about £100 and panel over 1,050). Visits 3/6 to 6/-. Semi-detached corner house (3 bedrooms), with separate surgery accommodation, garage and small garden, for sale. Premium two years' purchase.

33 LONDON, N.7.—Old-established mixed PRACTICE, about £1,365 p.a., in populous district. Panel about 400. Visits 3/6 and 5/-. majority. Semi-detached corner house (5 bedrooms), with small garden. Rent £100 p.a. Very good scope. Premium two years' purchase.

34 S. COAST.—Old-established middle-class PRACTICE, averaging £1,200 p.a., in first-rate residential town and health resort. Small panel. Visits 5/- to 15/-. House (7 bedrooms), to rent at £120 p.a. Scope. Premium two years' purchase.

35 S.W. OF ENGLAND.—FOURTH PARTNER required in mixed country town Practice of nearly £6,800 p.a. Panel 4,600. Share worth about £1,100 p.a. at two years' purchase. Partner must be young and have made special study of medicine. Preliminary Assistantship.

36 S.E. COAST.—PARTNERSHIP in non-dispensing Practice, about £4,500 p.a. Panel 1,400. Suitable house would

be available. One-fifth share at first at two years' purchase. Preliminary Assistantship. Scotsman preferred.

37 LONDON, W.2, and W.6.—Non-dispensing and non-panel PRACTICES run by two men in partnership. Receipts about £1,150 each practice. Premium two years' purchase and £1,000 respectively.

38 LONDON, N.W.—Steadily increasing PRACTICE in growing residential district within 14 miles of London. Receipts last year just over £700. Panel 470. Very attractive detached house (4 bedrooms), with good garden and garage, for sale or rent at £120 p.a. Branch close by to rent. Premium £1,250, or near offer.

39 LONDON, E.C.—City PRACTICE doing about £300 p.a. No visiting, pan- or midwifery. Premises to rent at £135 p.a. Premium £500.

40 SURREY.—PARTNERSHIP in old-established PRACTICE, averaging over £2,800 p.a., in outlying suburban district on the Thames. Small panel. Visits 5/- upwards. Outgoing partner's house (5 bedrooms, etc.), could be purchased if desired. One-third share at two years' purchase.

41 MIDLANDS. Cathedral City.—Old-established non-dispensing PRACTICE, averaging £1,550 p.a. Small panel. Visits 6/- to 10/6. Convenient house (about 6 bedrooms), in best residential part to rent at £65 p.a. Excellent prospects for one experienced in clinical pathology. Premium one and a-half years' purchase.

42 S. OF ENGLAND.—SURGICAL PARTNER required in good-class Practice in first-rate residential district. Applicant should be aged 30-35 or thereabouts, must hold the English Fellowship and be prepared to do some general practice. Modern up-to-date hospital. Share about £1,050 p.a. at first at two years' purchase.

43 BRITISH WEST INDIES.—SURGICAL PRACTICE in favourite town. Cash receipts, 1937, £1,682. Fine opportunity for experienced surgeon. Well-equipped nursing homes, X-ray and laboratory facilities. Rent of consulting rooms £5 monthly, and house £12 monthly. All kinds of sport. Premium £800.

44 S.E. COAST.—Old-established middle and working-class PRACTICE, about £950 p.a., in favourite summer resort. Clubs worth about £130 and panel about 1,490. Detached corner house (5 bed and dressing-rooms), with large garage and about half-acre of garden, for sale. Scope. Premium one and three-quarter years' purchase.

45 LONDON, N.W.—Old-established PRACTICE, doing over £1,100 in residential district under ten miles from Marble Arch. Select panel 305. House (5 bedrooms), with large garden and garage. Price freehold, £2,750, or rent £150 p.a. Scope. Premium £2,000.

46 NEW ZEALAND.—Eye, Ear, Nose and Throat PRACTICE in a most important commercial city. Cash receipts last year £2,277. Expenses light. Premium £2,460 cash or £2,600 terms (English currency). Purchaser should be at least 30 years of age with experience.

47 YORKS (N. RIDING).—Well-established country PRACTICE near small market town. Receipts, 1937, about £1,000. Panel 480 (approx.). Appointments £60. Fees 2/6 to £1 1s. Good house with 5 bedrooms, 3 reception rooms, etc., good garden and field, £65 p.a. Premium two years' purchase.

Purchasers can raise additional capital for the purchase of approved practices or shares. Particulars will be forwarded on application.

When
 you have a
 convalescent patient
 who is staying
 obstinately below par
 — a course of Numol
 will probably work
 wonders —

Expectant mothers, Nursing mothers, Babies who do not thrive, Growing children, Overworked students, Enfeebled old people are patients who have been found invariably to benefit from a course of Numol. And for children recovering from Whooping Cough, Measles, Mumps, Chicken Pox, and Fevers the period of convalescence will be shortened remarkably if Numol is given to the patient two or three times a day.

Doctors are invited
 to write for a
 free jar

RICE POLISHINGS CONCENTRATE

*Vitamin B₁ in
high concentration*

A dietetic substance of first importance. Presents an adequate supply of the anti-neuritic factor in relatively small bulk.

Satisfactory results may be expected to follow its administration in all cases of partial or complete Vitamin B₁ deficiency in patients of all ages. Stimulates appetite. Assists digestion. Promotes growth and increased alertness in children who lack weight and vigour.

The problem of SURGICAL STOCKINGS

Doctors who prescribe Compri-Vena Stockings are sure that the most beneficial support is given as each one is made to the patient's measurements and needs. They have long been recommended for Varicose veins and in conjunction with Injection Treatment as well as during and after Pregnancy. They are also invaluable in relieving undue leg strain. Compri-Vena Stockings are rubberless and yet elastic, are washable, cool in wear and invisible under ordinary silk stockings. They give real relief and preserve the shape of the legs. A skilled staff carefully follow all doctors' instructions. Full details from:

Compri-Vena

The Modern Shorts for the sedentary man

The new, close-fitting Linia Shorts are a boon to the man leading a sedentary life. Made of elastic tricot, they exert a gentle, beneficial massage on the abdominal area and give firm support. They are designed for wear instead of ordinary under-pants, and are light, easily laundered, porous and hygienic.

A development of Linia Shorts is Linia Reinforced Shorts which have a panel of firmer elastic over the abdomen for better support and control where there is a tendency to obesity.

You can order by post

Perfect fitting guaranteed or money refunded. We make a reduction of 2s. in the £ on purchases for personal use to members of the Medical Profession.

May we send you a fully explanatory booklet?

Prices

Linia Shorts: Popular Model, 25/-; De Luxe Model, 30/-; Standard Model, 17/6; in Wool, 25/-. Linia Reinforced Shorts: Popular Model, 40/-; De Luxe Model, 63/-; Standard Model, 25/-.

We shall be pleased to forward a specimen pair of Linia Shorts for your examination on approval.

Linia Shorts are on Sale Only at

J. Roussel, Ltd. (Dept. ME),

177, Regent Street, London, W.1

Telephone: Regent 7570.

And at 43, Cheapside, E.C.2, and five other London Branches.

ALUZYME NON-AUTOLYSED YEAST

Best for oral administration of Nuclein and the entire B Vitamin series.

For Vitamin B deficiency conditions, yeast is preferable to rice polishings and wheat germ preparations because it supplies all the members of the B Complex. Aluzyme is plain Brewers' yeast, stabilised by dehydration at a low temperature. This leaves the cells intact, and Aluzyme therefore provides all the essential constituents of yeast in the fully active state of living substance.

COMPARE THESE VALUES

Vit. B₁: 1140 International Units per ounce.

Vit. B₂ Complex: Maximum for dried yeast.

Nuclein Content: Four milligrammes per gram.

Glutathione Reaction: Brilliant magenta.

Microscope: 95% living cells. No foreign matter.

Flavin fluorescence test: Medium blue.

Specific in all forms of B avitaminosis. Valuable in toxæmias and as a general adjuvant in skin affections. Used with good results with calcium sulphide in furunculosis, with iron in anaemias, and with Thorpe's Mineral Phosphates in post-febrile asthenia.

Exclusively for medical use. No retail form. Bottles of 1,000 or 500 Tablets for dispensing. Samples on request.

BECKMAN'S TREATMENT IN GENERAL PRACTICE

*JUST PUBLISHED
NEW (3rd) EDITION*

FROM THE PREFACE

"The section on diseases of metabolism has disappeared as a result of placing diabetes mellitus, diabetes insipidus, and hyperinsulinism in the new section on endocrine disturbances and giving obesity and malnutrition a section of their own. There are also new sections on menstrual disturbances, diseases of the liver and bile passages, disturbances of water, salt and protein balance, disturbances caused by excessive heat, the anæmias, and blood disturbances other than the anæmias. Rheumatic fever, rheumatoid arthritis, osteo-arthritis and gout now have their own chapter in the infectious disease section."

"The following entities appear for the first time: Acidosis, Addison's disease, alkalosis, amenorrhœa, anorexia nervosa, celiac disease, colon consciousness, dehydration, drug allergy, epidemic dropsy, Gee-Herter-Heubner disease, hemiplegia, hypomenorrhœa, idiopathic steatorrhœa, infantile diarrhœa, insomnia, intermenstrual pain, Ménière's disease, menopause, menorrhagia, metrorrhagia, myasthenia gravis, nontropical sprue, nutritional œdema, oligomenorrhœa, osteomalacia, otitis media and complications, para-nasal sinusitis, phlebitis, physical allergy, pompholyx, proctalgia fugax, progressive muscular dystrophy, prophylaxis of venereal diseases, renal rickets, torulosis, unstable colon, visceroptosis, von Gierke's disease, xerophthalmia."

THE BOOK OF WHICH "THE LANCET" SAID:

"This book, or its equivalent, should be in the hands of every physician, and we have not yet come across its equivalent."

By HARRY BECKMAN, M.D., Professor of Pharmacology at Marquette University School of Medicine. Octavo of 787 pages. Cloth, 42s. net.

GIFFORD'S TEXTBOOK OF OPHTHALMOLOGY

NEW, COMPACT AND COMPLETE

This new book, written specifically for the general practitioner as well as for the ophthalmologist, is based on the author's long teaching experience and a wealth of clinical material. The whole subject is logically presented in a compact form, fully illustrated with coloured and black-and-white illustrations. It is definite on diagnosis; specific on treatment.

By SANFORD R. GIFFORD, M.A., M.D., F.A.C.S., Professor of Ophthalmology, Northwestern University Medical School, Chicago. 12mo. of 492 pages, with 249 illustrations and 11 coloured plates. Cloth, 18s. net.

*"My patient finds this instrument
THE BEST HE HAS TRIED"*
writes a well-known Aurist

The range of models, all most moderate in price, includes types with carbon or crystal microphones, and with two or three stages of valve amplification; earpieces to choice. Pocket Model - 52 P.L. illustrated, measures 6" x 5" x 1 1/2".

From every hand comes remarkable testimony to the exceptional merits of the Maxade Hearing Aids. Here is a recent letter from a user, L.A.L., of Erith, Kent, who writes:—

"I have suffered with partial deafness for 20 years. I have had two other instruments, and have tried five others. Only one of them could compare with the one I bought from your firm . . . and that was more than double the price."

FOCUSED TONE

Maxade is the ONLY hearing aid with simple, sensitive controls that enable doctors or patients to adjust pitch and volume to suit perfectly the individual degree of deafness and the particular sounds they wish to hear—even without auditory tests. Moreover, unpleasant, extraneous noises can be "tuned out." Combined with bone or air conduction, Focused Tone achieves the nearest approach to natural hearing that can be secured. Any Maxade model will gladly be supplied for free clinical test.

MA' ADE

HEARING AIDS

ENTERED UPON THE APPROVED LIST OF THE NATIONAL INSTITUTE FOR THE DEAF AND CONSISTENTLY RECOMMENDED BY THE PRINCIPAL HOSPITALS;

ACOUSTICAL ENGINEERS SINCE 1919.

Spencer Corsets Are Individually Designed for these Six Conditions

HERNIA

For cases of inoperable hernia a Spencer provides support with real comfort and safety. A Spencer will control a reducible hernia and restore the patient to reasonably normal activity, if operation is inadvisable.

ENTEROPTOSIS and INTESTINAL STASIS

Where these conditions are known to exist and support is needed, a Spencer Support is an accepted corrective measure. A Spencer supports the organs as nearly as possible in normal position and effects a marked posture improvement.

SACRO-ILIAC STRAIN and LUMBO-SACRAL STRAIN

Spencer Supports are designed to effect immobilization of the involved joints and to improve posture. In many instances the conditions are immediately and successfully relieved.

MATERNITY

Spencer Maternity Supports fit perfectly, provide gentle support and restful comfort. In many cases they relieve nausea and backache, when not pathological, and lessen or control sacro-iliac and lumbo-sacral strain.

MOVABLE KIDNEY

A Spencer Support for movable kidney is designed to support the abdomen from below, upward and backward. It is also prescribed to elevate the kidney in cases of nephroptosis. A kidney pad is provided when prescribed by doctors.

POST-OPERATIVE

Many leading surgeons prescribe either the Spencer Abdominal Supporting Belt or Supporting Corset for post-operative convalescence, as a precaution against accident or injury.

Because each Spencer is individually designed and made from the actual measurements and posture description of the patients, exact fit and restful comfort are ensured, and the garment will not ride up or slip out of place. All Spencers are designed to improve posture, provide abdominal uplift and place the pull on the pelvic girdle, not on the spine at, or above, the lumbar region. They unite accepted surgical features and fine style lines. Spencers improve appearance, are light in weight, flexible, easily washed and are guaranteed NEVER to lose their shape.

BEWARE OF SUBSTITUTION.—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support, a corset of another make has been substituted, and, because its makers do not understand the Spencer principles of individual designing, has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

Trained Spencer Corsettières are resident throughout the Kingdom. Name of nearest gladly supplied on request.

A scientifically trained Spencer Corsettière will call at your surgery or at your patient's home to take measurements under your supervision.

DESOUTTER

CASE RECORDS

Case No. H2354/1673. 1936

The patient was suffering from muscular hypertrophy of the right leg; the circumference of the calf being twice, and the ankle nearly three times, that of the sound limb. The foot was deformed, necessitating a special shoe, and the patient's walk was most ungainly. (Fig. 1.) At the request of the surgeon, Mr. Desoutter examined the patient in hospital before amputation to give his opinion as to:—

- 1 *The best site of amputation in view of the peculiar difficulties of the case.*
- 2 *The prognosis from the points of view of appearance and ability to walk well with an artificial limb.*

It was decided to amputate 7" below the knee joint and to remove the hypertrophied muscle on the inner side of the leg. Figure 2 shows the great success with which the operation was performed. The scar on the inner side of the leg, extending from the end of the stump to just under the knee, seemed at first to need special attention, but by very careful

fitting of the artificial limb serious trouble was avoided. Careful physical re-education played a large part in the success of this case, and the patient now walks very well and has a natural appearance.

Prescribing with Confidence

The advantages of Rhinitol in the treatment of

COLDS

NASAL CONGESTION and CATARRH

and all other affections of the upper respiratory tract are:—

1. Its very low ephedrine content.
2. Its property of emulsifying with body fluids owing to the vasogen vehicle.
3. Its complete freedom from irritant or toxic effects.
4. Its rapid yet prolonged action.

'Panopepton'

In Refractory Cases

TO USE 'PANOPEPTON' in a case that has been proving refractory to both treatment and management is often to bring about an immediate change for the better in all the conditions—especially where there has been difficulty in getting nourishment adapted to the taste and toleration of the patient.

'PANOPEPTON' is well designed to meet the essential desiderata of a food for the sick—in agreeability, assimilability, and substantial peculiar nutritive value.

'PANOPEPTON' presents, in a form ready for absorption, the entire nutritious substance of beef and wheat. It is a complete solution of all the nutrient, savoury and stimulant, nitrogenous and inorganic constituents of these typical foods.

Supplied in 12-oz. bottles.

A Free Sample will be sent to Members of the Medical Profession on request.

Euphyllin increases the rate of flow of the blood through the heart, and even if very much diluted the average increase, compared with similar drugs, is as follows—

THEOPHYLLINE, 31%

CAFFEINE, 32%

EUPHYLLIN, 82%

On account of its vasodilatory action on the peripheral circulation, which greatly exceeds that of all other purine compounds, *Euphyllin* is particularly suited to the treatment of Coronary Sclerosis, Angina Pectoris, and Degeneration of the Cardiac Muscle.

SPECIAL LITERATURE AND SAMPLES WILL BE FORWARDED ON REQUEST.

THE NATURAL MINERAL WATERS OF

KARLSBAD

Sprudel, Muhlbrunnen, and Schlossbrunnen

These waters act :

- (1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.
- (2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of

Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary Organs.

Bottled under Official Supervision at Karlsbad and regularly imported by the Sole Agents:

INGRAM & ROYLE, Ltd.,
BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.
And at LIVERPOOL and BRISTOL.

Samples and Descriptive Pamphlet forwarded on application.

Vapo-Cresolene

ESTD 1879

produced from Vapo-Cresolene by the Cresolene Vaporiser exert a direct germicidal action when in contact with moist surfaces harbouring pathogenic bacteria associated with respiratory affections. Sedative, anti-spasmodic and penetrating, Vapo-Cresolene may be used to maximum advantage while the patient sleeps. Vapo-Cresolene has enjoyed its reputation as a dependable inhalant for over 57 years and is invaluable for the treatment of children.

MANDECAL

(Compound Calcium Mandelate B.D.H.)

The report of the results of clinical trials on a series of 33 hospital patients with Mandecal (*Lancet*, February 26th, 1938, p. 494) confirms the general opinion formed of this product during its use as a urinary antiseptic in the ordinary routine of clinical practice during the past six months.

Mandecal is equal in bacteriostatic and bactericidal effects to other salts of mandelic acid and at the same time it

is markedly less irritating and less nauseating. Physicians may prefer to continue to prescribe Mandelix (Elixir of Ammonium Mandelate B.D.H.) in most cases, but for hypersensitive patients who may be unduly nauseated by Mandelix, Mandecal approximates to the ideal urinary antiseptic.

Mandecal is issued as a readily miscible powder; it is available in bottles each containing sufficient for treatment lasting seven days.

Indications for Nestrovite

"By no other means will so much human suffering be banished as by the correct understanding and employment of vitamins." (Szent-Györgyi, *Lancet*, December 18th, 1937.)

PREGNANCY & LACTATION

Health is endangered unless all dietary requirements, including vitamins, are met.

CHILDHOOD

"Nestrovite" Emulsion or Tablets throughout the school age provide for development and protection.

GASTRO-INTESTINAL DISORDERS

"Nestrovite" should be included in the treatment.

INFANCY

"Nestrovite" Emulsion is recommended in place of cod liver oil and orange juice.

CONVALESCENCE

An ample supply of the vitamins contained in "Nestrovite" is necessary.

LOWERED VITALITY

Lowered vitality is likely to be due to lack of vitamins A, C, and D. "Nestrovite" corrects this.

NESTROVITE

Trade Mark

Vitamin Tablets and Emulsion

Brand

"Nestrovite" Tablets in boxes of 20 and 100. Emulsion in bottles of 4½ fl. oz.

the scientific contraceptive

MIL-SAN is submitted to members of the medical profession who are interested in the control of conception, in the firm belief that it is the most effective contraceptive produced in the light of present-day medical knowledge. Further that it is non-injurious, unobjectionable and hygienic in use and simple to apply.

A booklet and medical specimen pack are sent, on request, to members of the profession. Information regarding the basis of the formula, the ingredients, the tests made and the action and behaviour of the product are set out fully,

while the specimens sent demonstrate clearly the simplicity and advantages of the application method. There are no contra-indications to the use of MIL-SAN with a dependable condom or a properly fitted occlusive pessary. It is only by such combined use that the consequences of misuse of one or other of the methods can be minimized and the maximum practicable security obtained. MIL-SAN is on the N.B.C.A. Approved List for use with a cap or condom.

Please write name and address plainly or send card or note heading when requesting particulars and specimen tubes.

OVALTINE

IN NUTRITIONAL CRISES

WHILE the average adult is able to maintain a healthy existence on the ordinary everyday diet, there are certain periods in the life of each individual when an increased demand for the vital food elements arises. Outstanding examples are the period of adolescence, the pregnant and nursing states and the stage of convalescence after severe and lowering illnesses.

"Ovaltine" is an eminently satisfactory adjunct to the ordinary dietary at all such times. Composed of fresh, full-cream milk, eggs and malt extract in proportions adjusted to meet physiological requirements, it provides, in an agreeable form, calcium, phosphorus, vitamins and other important food elements.

"Ovaltine" is a metabolic stimulant and digestive which aids the assimilation of other foods and promotes general good health. It can, therefore, be taken regularly with advantage in place of tea, coffee, or other beverage. A noteworthy feature is its delightful taste which is appreciated by people of all ages.

A liberal supply for clinical trial sent free on request.

Whooping Cough is under control . . .

Extensive trials of the Whooping Cough Dissolved Vaccine G.L. in public and private practice confirm that effective control of this disease is now possible. When inoculated prophylactically with the Dissolved Vaccine G.L., a great proportion of contacts have escaped the disease. And actual cases, when treated at the first sign of paroxysmal cough, have also consistently responded to therapeutic injection, the disease being frequently aborted or the duration of illness considerably shortened.

In the Dissolved Vaccine G.L. the antigens are (a) *in solution*, giving rapid immunity response; (b) *detoxicated*, permitting adequate dosage without undesirable reactions.

WHOOPING COUGH DISSOLVED VACCINE-G.L.

Prices: Rubber-capped bottles: 5 cc., 10/9; 10 cc., 15/6; 25 cc., 25/- Less usual professional discount.

ACRIFLAVINE PREPARATIONS BOOTS

IN A RECENT ARTICLE ON THE USE AND ABUSE OF ANTISEPTICS (Brit. Med. J., Dec. 18th, 1937, page 1233) SPECIAL ATTENTION IS DIRECTED TO ACRIFLAVINE AND RELATED ACRIDINE COMPOUNDS

"These are the only substances which have been proved by controlled animal experiment to be capable of averting wound sepsis. They kill or prevent the growth of pyogenic cocci in extreme dilution, act slowly, and in some cases are more bactericidal in serum—a unique property. They are also relatively non-toxic, sufficient concentrations for antiseptic action demonstrably leaving the activities of leucocytes unimpaired; this property is also unique. It is therefore possible to infiltrate tissues with solutions in order to prevent infection or to arrest it at an early stage."

Preparations of Acriflavine and Neutral Acriflavine are available in the form of Emulsion, Cream, Tablets, Solution Tablets, Medicated Gauze, Pessaries, Bougies & Pigment.

Full particulars and literature will be sent on request.

MILTON

DETERGENT
PENETRATIVE
GERMICIDAL
OSMOTIC
NON-TOXIC
LIQUEFACTIVE
REGENERATIVE

1. DETERGENT

It dissolves necrotic animal tissue and decomposes (by oxidation) organic toxins, the odours of which are instantly destroyed.

2. PENETRATIVE

Its action is not merely superficial but extends deep into the tissues.

In hardened agar it has been proved to penetrate to a depth of $\frac{1}{2}$ inch in 48 hours.

3. GERMICIDAL

It acts lethally on all the common pathogenic organisms found in wounds and infected areas generally, with a Hygienic Laboratory coefficient for *B. typhosus* of 4.98.

Other typical coefficients are:—

B. Coli communis	2.12
B. tetani	1.34
B. anthracis (spores)	2.66
B. enteritidis	2.12
B. influenzae (Pfeiffer)	2.65
B. tuberculosis	2.17

4. OSMOTIC

Like all hypertonic salines, it acts osmotically promoting leucocytosis and reducing œdema.

5. NON-TOXIC

It is bland to living tissue and (in contrast to other hypochlorites) contains no caustic element. 50% Milton applied to delicate cutaneous tissues for one hour was shown to have no irritant effect.

6. LIQUEFACTIVE

In contrast with most chemical antiseptics, it does not coagulate proteins, except at full strength. 10% Milton shows no coagulation with saliva or horse-serum. Even the proteins insoluble in water, as myosin and fibrinogen, are readily soluble in Milton.

7. REGENERATIVE

It has the almost unique property of stimulating the growth of new tissues.

1% Milton has been shown to increase cell-division in tissues beyond the normal, thereby accelerating the healing process.

These properties indicate clearly the mode of using Milton, e.g., for wounds and lesions generally:

(a) Cleanse the wound thoroughly with fairly strong Milton, frequently applied and freely used. In this process Milton is "unactivated" by dissolving and removing necrotic tissue, leaving sodium chloride only.

(b) Cover the clean wound with a Milton pack, changing frequently. Here its germicidal and osmotic properties come into action, assisted by absence of causticity and coagulation.

(c) On commencement of healing, reduce the strength of the Milton gradually. Under such rational treatment, it is rarely that a fresh wound heals otherwise than by "first intention".

**MILTON IS SUPPLIED AT A STANDARD STRENGTH
READY FOR IMMEDIATE USE, AND IS STABLE.**

**MILTON IS SAFE FOR EITHER EXTERNAL OR INTERNAL
APPLICATION.**

The distinctive qualities of this carefully designed preparation and its superiority over other "hypochlorite" antiseptics—e.g., Dakin's fluid (Liq. sod. chlorinate) and Eusol—have been clearly demonstrated by special Laboratory researches, the results of which have been amply confirmed in practical use. Copies of these reports and a sample of Milton will be forwarded to any medical practitioner on request.

Measles Control with

IMMUNE GLOBULIN (HUMAN)

Lederle

BECAUSE of the frequency of complications, the mortality rate of measles is high—higher than that for whooping cough, diphtheria and scarlet fever.

Complications can be avoided by the use of IMMUNE GLOBULIN (HUMAN) *Lederle*, particularly those of Broncho-pneumonia—responsible for about 50% of deaths in the infant age group (6 months to 3 years).

As a modification dose, one injection of 2 cc. is administered to patients in the infant age group from 6 to 8 days after exposure (for children in the same family this is 2 to 4 days after the appearance of rash in the exposing child). This dosage confers an active and lasting immunity in the majority of cases. For passive immunity of several weeks, a first dose of 2 cc. of IMMUNE GLOBULIN (HUMAN) *Lederle* is administered as soon as contact has been recognized; a second dose of 2 cc. four days later.

THE COMPARATIVE VALUE OF ADULT SERUM, CONVALESCENT SERUM, AND IMMUNE GLOBULIN PATIENTS TREATED FOR PROTECTION OR MODIFICATION

ALL TYPES OF EXPOSURE

Procedure	Cases	Per Cent. Protected	Per Cent. Modified	Per Cent. Failed
Adult Serum ...	584	56.4	23.8	19.8
Convalescent Serum ...	1,627	75.4	16.8	7.8
Immune Globulin ...	1,341	71.5	23.9	4.6

Eley, R. C., N.E. Journ. Med., Aug., 1935, 213, 195.

IMMUNE GLOBULIN (HUMAN) *Lederle* is distributed in 2 cc. vials and 10 cc. vials.

Cod Liver Oil

is the Liver Oil with the

**OFFICIAL BACKING OF THE MINISTRY
OF HEALTH AND LEAGUE OF NATIONS
NUTRITION COMMITTEE**

As every practitioner knows, no other liver oil has such a record of achievement as Cod Liver Oil. For it contains Vitamins A and D in the right proportion. In fact, the study of vitamins originated through Cod Liver Oil. Its only drawback in the past has been its taste. Now this difficulty has been overcome. "SevenSeaS" provides, for the first time, Cod Liver Oil in a palatable form—so palatable that it can be taken with ordinary foods, and it is available in "High Potency" form, too.

"SevenSeaS" is obtainable in three forms: (1) "High Potency" Oil—four times "B.P." standard; (2) "High Potency" Capsules containing 5 mm. dose of "High Potency" Oil; (3) Standard "B.P." Oil. We would like all practitioners to prove "SevenSeaS" "High Potency" Cod Liver Oil to their own satisfaction. Please send to the address below for a free sample.

Pediatricians

approve these purées

A range of Strained Foods giving maximum nutritive values

THE nutritional value of vegetable purées for infants and soft diet cases is receiving the endorsement of the medical profession to a very marked degree.

Hitherto the difficulties and deficiencies of home preparation—inefficient sieving and destructive oxidation—not to mention the tedium and labour involved—have hindered practical application, but the introduction of a complete range of strained foods by H. J. Heinz Co. Ltd. has been universally accepted as the solution of this problem.

H. J. Heinz Co. Ltd., with their exceptional experience in food preparation, have recognised the legitimate possibilities of supplying strained foods of that maximum nutritive value, uniformity and convenience which only good factory practice can achieve.

The vegetable and fruit purées of H. J. Heinz Co. Ltd. are prepared under conditions of the most scrupulous care with special reference to minimising mechanical loss of mineral salts and other soluble nutriment. The edible portions are washed and trimmed and then cooked under light steam pressure until in perfect disposition for comminution by extrusion and cutting. All mineral salts, vitamins and other soluble nutriment are retained, while harsher fibres, if any, are so reduced as to be non-irritant. The raw materials are purchased when and where seasonal and regional conditions of growth are most favourable, and only fresh gathered vegetables of the highest quality are used.

After the straining process the purée is adjusted to a proper solid content convenient for marketing. Absorbed air is removed and sealing *in vacuo* follows in specially prepared enamel-lined containers. The process concludes with high-temperature sterilisation.

PROTEIN	4.5
CARBOHYDRATES	8.8

LIVERPOOL and LONDON

"Vitamin B₁ deficiency an outstanding fault in the diet of many millions of people"

(British Medical Journal, 16 Oct., 1937, p. 753)

The reduction in Vitamin B₁ intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent., and may be as much as 70 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B acts as a limiting factor in the maintenance of health and nutrition, and often

results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, contributes to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

1. For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

2. The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 200 International Units, an amount sufficient to raise a deficient diet to an optimal level.

3. The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamins B₂ and B₆, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

4. Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B₁ activity with no addition whatsoever.

BEMAX

A unique natural source of accessory nutritional factors.

VITAMIN B₁ IN FOODS

Biochemical J., 1935, and other sources

The figures represent International Units per ounce.

Laboratory reports on Bemax, and a clinical sample for personal trial sent on request.

The Bemax Laboratories (Dept. B.55), 23, Upper Mall, London, W. 6.

POST-FEBRILE CONDITIONS

ENTERIC FEVER: By adding 'Sanatogen' to boiled and cooled milk the author found, in the dietetic treatment of typhoid (enteric) fever, that digestion and assimilation were easily accomplished, positive evidence being furnished by the steady improvement of his patients.

"Dietetic Treatment of Enteric Fever."
(PUBLIC HEALTH.)

INFLUENZA: "As a tonic-food 'Sanatogen' stands for pre-eminence. This is no mere expression of an individual opinion, but a fact firmly established by a vast array of clinical experience. . . . Whatever dietary may be decided on in the post-febrile period of influenza, it must always include 'Sanatogen.'"

(—J.D.)

DIPHTHERIA: "I am finding your Casein Glycerophosphate of great service to my patients in the Infectious Diseases Hospital, especially to Diphtheria cases who are put on it as a routine."

(—M.R.C.S., L.R.C.S., D.P.H.)

SCARLET FEVER: "I weighed, weekly, eleven children convalescent from scarlet fever to whom 'Sanatogen' was given, and fourteen other convalescent children of about the same ages, in as nearly as possible the same condition, living in hospital at the same time, and getting the same food. I found that the average gain in the weight of the children getting 'Sanatogen' was, in five weeks, 4 lbs. 2 ozs., and of those not getting 'Sanatogen' was just under 3 lbs. I have also weighed the same child at one time when not taking 'Sanatogen,' and at another when taking 'Sanatogen,' and I invariably found that the child improved considerably, and gained more weight when 'Sanatogen' was given in addition to its ordinary diet."

(THE PRACTITIONER.)

★ ★ ★ ★ ★ ★ ★ ★ ★ ★ ★ ★ ★ ★ ★ ★

"The bactericidal action of the blood and its naturally protective powers against diseases are developed by 'Sanatogen.' The combination of a glycerophosphate with albumin, as it exists in 'Sanatogen,' produces a true physiological influence on nutrition."

URINE

CALCIUM

THE BUILDING BLOCKS OF LIFE

Foods, the building blocks of life, are not devoid of demands upon the organism. Some of them, necessary for cell-growth and repair, produce an acid residue that must be neutralized

Normally, the alkaline ash foods are adequate for this purpose. But when acidosis complicates disease, food is not enough. The administration of alkalies is necessary.

Acidosis of the non-ketogenic type readily yields to alkalization with Alka-Zane, as it supplies sodium, potassium, calcium and magnesium in proper proportions for quickly replenishing and efficiently maintaining the alkali reserve.

Alka-Zane contains carbonates, phosphates and citrates only — no tartrates, lactates or sulphates and no sodium chloride.

Alka-Zane is supplied in 4-oz. bottles.

Research.... in Therapeutics

The research work undertaken by Parke, Davis & Co., since the establishment of the firm more than half a century ago, has resulted in the introduction into medicine of many admittedly valuable therapeutic agents. Prominent among these have been ADRENALIN, PITUITRIN, CASCARA SAGRADA and VENTRICULIN.

To Parke, Davis & Co. there must also be credited the application, for the first time, of chemical standardization of drugs which was begun in 1882, and later in 1895 of physiological standardization of non-alkaloidal products which gained official recognition thirty-seven years later in the British Pharmacopœia, 1932.

Research is being carried on continuously and necessarily over a widened area. In the Research Laboratory a staff of about 70 persons is engaged on this work, months, and sometimes years, being devoted to the completion of an investigation which may even then prove fruitless.

Examples of successful research work are furnished by investigations on the hormones of the pituitary gland which resulted in the introduction of PITOCIN, PITRESSIN, ANTUITRIN "S" and ANTUITRIN "GROWTH."

Parke, Davis & Co. are definitely committed to a perpetuation of this long-established policy of scientific research which may be expected to lead to equally important developments in the future.

LABORATORIES · HOUNSLOW · MIDDLESEX

INC. U.S.A., LIABILITY LTD.

In Children's Head Colds

IN 100 cases of acute rhinitis in children from 2 months to 12 years of age treated with Benzedrine Brand Inhaler, two observers report prompt and adequate shrinkage of the nasal mucosa in 97%. The vapour form of treatment—in addition to its greater effectiveness—overcomes the objections which children show to liquid inhalants. (*Arch. Pediat.*, 54:97, 1937.)

For the adult members of the family, Benzedrine Brand Inhaler is equally useful. Untoward effects are negligible, ciliary action is not inhibited, and the vapour, by diffusing throughout the entire upper respiratory tract, "often helps to abort or shorten conditions that would otherwise proceed to more serious complications." (*Clin. Med. & Surg.*, 44:25, 1937.)

CRUNCHY FOODS AND THE TEETH

Crisp, fibrous foods are generally considered to perform a useful function in scouring the teeth, thus keeping them free from sticky food particles, which are apt to ferment and cause decay. The plentiful saliva, which hard, dry foods produce, is also of value in cleaning the mouth.

Furthermore the vigorous mastication that hard foods demand is generally held to assist the growth and correct development of the jaws.

For these reasons many practitioners recommend that the normal diet should include a proportion of hard, dry foods. They find that Ryvita eaten daily has a beneficial effect upon the teeth, especially those of children. Free samples of Ryvita for distribution to patients will gladly be supplied on request.

PROTECTS *Against Infection*

In comparative studies made under properly controlled conditions, Metaphen has been shown to be from 2.6 to 1,500 times more germicidal against *staphylococcus aureus* than five other commonly employed antiseptics, including mercuric chloride and tincture of iodine. Against other common pathogenic organisms, Metaphen also demonstrated its marked superiority over all of the drugs tested. Furthermore, Metaphen was found to be 10% more effective for surface skin disinfection and 87% more effective for deep skin disinfection than tincture of iodine. (*Annals of Surg.*, 93:587-597.) In addition to its great

bactericidal power, Metaphen has other important advantages. It is non-toxic and non-irritating; does not coagulate serum or tissue albumins; and its solutions are stable when exposed to air. Metaphen is supplied through pharmacies in a variety of useful forms, including TINCTURE METAPHEN, METAPHEN 1:500 SOLUTION and METAPHEN 1:2,500 SOLUTION. Requests for professional literature are invited.

Her temperature is 103. Even when in normal health she is not very strong, and the weakening effect of the fever is becoming pronounced—especially as she refuses most of the light diet offered to her.

In such cases the unique properties of Brand's Essence are of special benefit. This pure meat stimulant does not cause thirst. Its flavour has been found to tempt the most enfeebled appetite and restore food tolerance at times when the mere suggestion of food was repugnant to the patient.

Brand's contains no solids or irritants of any kind and is assimilated with rapid ease by the weakest digestion. Its protein-sparing properties are pronounced.

BRAND'S CHICKEN OR BEEF **ESSENCE**

is never contra-indicated

BRAND & CO. LTD., SOUTH LAMBETH ROAD, LONDON, S.W.8

IN ILLNESS AND CONVALESCENCE

When the digestive powers are weak or impaired Allenburys Diet is pre-eminently suitable as a basis of feeding. Entirely distinct from Allenburys Foods for Infants, the Diet is made from pure, rich, full-cream milk and whole wheat, partially pre-digested during manufacture. Vitamin D is added. The delicate flavour of the Diet may be varied by the addition of coffee, cocoa, etc.

In tins, 2/1, 4/- and 7/6.

Clinical trial sample will be sent post free on application.

EFFICIENCY ESTABLISHED BY BIOLOGICAL TESTS AND CLINICAL USE

AN EXTRACT OF ADRENAL CORTEX FOR THE TREATMENT OF ADDISON'S DISEASE

AND OTHER CONDITIONS

EUCORTONE is an extract of adrenal cortex, containing the hormone, cortin. It is highly successful in Addison's disease. Particularly striking is its rapid restoration of appetite, weight, strength, and feeling of well-being.

Successes have now been reported from the use of adrenal cortical extract in various other conditions, including neurasthenia, psoriasis, and hyperemesis gravidarum.

IN ACUTE TOXÆMIA OF BURNS—*Lancet*, 1936, June 20th, p. 1400.

Three cases of acute toxæmia from burns were treated with EUCORTONE and recovered. In two of the cases, death within a short time could have been predicted almost certainly. In the investigators' experience of these conditions, recovery under any methods of treatment previously used had not occurred. The investigators attributed the recovery in these cases with every confidence to EUCORTONE.

EUCORTONE is biologically standardized on adrenalectomized animals. It has now been further purified and concentrated. It is practically free from nitrogen and adrenaline, contains no irritant or toxic substance, and is sterile. One c.cm. of the extract is equivalent to 75 grams of adrenal cortex or about 110 grams of the whole gland. EUCORTONE is administered intramuscularly, intravenously (in crises), and subcutaneously (in chronic cases).

SOME RECENT WORK IN EXPERIMENTAL CANCER RESEARCH*

BY

W. E. GYE, M.D.

Director, Imperial Cancer Research Fund

The pioneers of cancer research, especially Borrel, were well aware that the study of transplanted tumours is only the study of cells which are already "cancerized," and can throw no light on the complex changes that occur when a cancer forms. It was clearly understood that the aetiology of cancer is divisible into two parts: the causes which lead up to the occurrence of a tumour and the cause which explains the property of the malignant cell. This distinction is not artificial or merely plausible, invented to explain an apparently irrational multiplicity of facts concerning cancer. It is a deduction from general pathological observations, and is now a self-evident conclusion from recent work with carcinogenic agents. Clinically it has long been known that epithelioma of the skin may develop as a consequence of the action of tar, pitch, lubricating oils, or x rays on the skin; and that the autonomous growth of the malignant cells is independent of the action of the tar or oil or other causative agent, since the metastases, remote from any possible action of the causative agent, behave as malignant cells. Further, a tumour brought into existence by applying a carcinogenic agent, chemical or physical, can be transplanted indefinitely in normal animals of the same species. Thus the agent which is responsible for starting a tumour plays no further part in the progress of the disease once malignancy has occurred. This distinction between causes which act on normal cells and lead to malignant transformation and the intracellular cause which is responsible for malignancy is not fanciful; it is a necessary deduction from universally accepted facts. Ewing has designated these processes as the "causative genesis" and the "formal genesis" of cancer. The simpler terms "remote causes" and "the proximate cause" are perhaps preferable. Included under the term "remote causes" are the very numerous chemical substances, radiant energy, and gross parasites which have been proved capable of initiating new growths. The second part of cancer aetiology, the proximate cause, gives rise to keenest discussion and will be dealt with later. The advances in our knowledge may be conveniently grouped under these respective terms.

Remote Causes of Cancer

It is now common knowledge that cancer can be started at will by the application of one or other of the "carcinogenic agents." This knowledge has robbed cancer of much of its "mystery" and has helped to create a healthy optimistic outlook in research. It has demonstrated that the sort of investigation which has proved so successful for other diseases can lead to great advances in our knowledge of cancer.

Space does not permit of even a brief survey of the carcinogenic agents. They are already numerous and are being added to every year. In this field of research clinical observation has usually anticipated laboratory experiment. Percivall Pott more than 150 years ago observed that chimney-sweeps suffered excessively from scrotal cancer, and attributed this to soot. That x rays may induce epithelioma was proved by the pioneer radiologists, and the causative association of parasites with cancer was observed long ago in bilharzia. Laboratory investigations have amplified and extended these observations. They have led to the preparation of pure chemical substances which can induce cancer formation, and have given rise to fruitful working hypotheses. A whole series of carcinogenic hydrocarbons with a phenanthrene nucleus have been discovered by Professors Kennaway and Cook and their collaborators. One of these compounds, methyl cholanthrene, can be obtained from bile acids by chemical transformations theoretically possible in the body. Moreover, these carcinogenic substances are related chemically to oestrone, to cholesterol, and to other substances which are naturally present in the body. The hypothesis that all cancer-producing substances possess the phenanthrene nucleus is not, however, tenable: Japanese pathologists have been successful in inducing cancer with aniline dyestuffs.

Yoshida has proved that *o*-amino-azo-toluene induces hepatic cancer in rats which are fed with the substance dissolved in olive oil. Kinoshita has shown that dimethyl-azo-benzene—"butter-yellow," so called because according to Kinoshita it is used commercially as a colouring matter in butter—likewise causes cancer of the liver when fed to rats. He found that 176 mg. fed over a period of fifty days was the smallest dose able to give rise to a hepatoma. These substances, administered by mouth, are probably changed by the liver and excreted in an altered form. Thus *o*-amino-azo-toluene is known to be broken up and eliminated as *p*-acetyl-toluylenediamine in the urine. Butter-yellow, fed to rats, is detectable in the liver, and to a less extent in the kidneys and spleen: elimination from the body is not easy, but it is probably broken up and partially excreted as dimethyl-*p*-phenylenediamine.

The induction of cancer by means of oestrone is of exceptional interest because its mode of action has given us a glimpse of what may be described vaguely as an internal carcinogenic environment. The story begins with the study of heredity in cancer, which led to the production by inbreeding of strains of mice in which 70 per cent. or more of the females died of cancer of the breast. Leo Loeb, working with such a strain, showed in 1916 that when very young females were ovariectomized the percentage of cancer fell significantly. His observations were confirmed by Cori and later by W. S. Murray, who

missible with cell-free extracts. The object of the work was, in other words, to put to the test of experiment the thesis that dibenzanthracene or similar agents act upon cells by sensitizing them to the action of a virus. It may be stated at once that all attempts to transmit this tumour with cell-free extracts have failed, though it can be propagated fairly easily with living cell grafts. In some of the experiments in which these tests were made it is not even justifiable to use the term "cell-free extract," for it has repeatedly been found that a saline extract which has been spun for a few minutes at 5,000 revolutions is incapable of giving rise to a growth. This artificially induced sarcoma therefore differs in no wise from tumours of mice and rats. It has one great advantage as material for experimental study, since it is possible to test in an indirect way whether the cells, though providing no direct evidence of the presence of a virus, do or do not contain an antigen related to the infective agents of filterable fowl tumours. We cannot make such tests with either spontaneous or artificially induced tumours of rats and mice because we have no filterable rat or mouse tumours to provide virus to test immune sera. The experiments carried out by Foulds were briefly as follows. Rabbits were bled in order to obtain samples of normal serum and were then injected repeatedly with Berkefeld filtrates of the dibenzanthracene tumour. After a time it was found that the sera of the rabbits acquired an antibody which neutralized completely the virus of the Rous sarcoma. This was proved by mixing the serum with active filtrates of the Rous sarcoma, the control being a similar mixture of active filtrate and serum taken before the immunizing injections were made; the mixtures were incubated at 37° C. for an hour and then injected in different sites of four chickens. In the sites where mixtures containing immune serum were placed no tumours developed, whereas in the control sites large rapidly growing Rous sarcomas formed.

It is clear from the experiments, which have been fully described by Foulds (*Amer. J. Cancer*, 1937, 31, 404), that although a filtrate of the dibenzanthracene tumour is inactive—that is, is unable to provoke tumour formation—it nevertheless contains an antigen which is capable of giving rise to antibodies that readily neutralize the virus of the Rous sarcoma. That this antigen is not some indefinite component of normal chicken tissues was proved in several ways—for example, by attempting and failing to absorb the antibody by means of chicken tissue, and by attempting and failing to produce a similar antibody by injecting rabbits with extracts of normal chicken tissues. There is therefore something closely related to the infective agent of the Rous sarcoma in these inactive filtrates of a dibenzanthracene tumour. Whether it is a virus or part of a virus we do not yet know. For the present it is sufficient to emphasize that these experiments are a warning against too confident and too dogmatic conclusions which may be drawn from negative results of filtration experiments.

A comment on criticisms of this work may be allowed before passing on to a brief account of work on rabbit papillomas. It has been objected that the virus which is present in the dibenzanthracene tumour may be merely carried in the tumour passively, as a passenger is carried in a train—that it is unrelated causatively to the tumour. The foundation of this criticism lies in the well-known fact that viruses can be made to lodge in tumour growths—for example, the virus of vaccinia can be carried by mouse tumours. It is inferred from this fact that it is possible, if not probable, that a dibenzanthracene tumour growing in a chicken attracts virus which may normally exist in chicken tissues and provides suitable conditions for

the existence, and presumably for the growth and multiplication, of the virus. If this were so the production of immune sera by the methods employed would be misleading. This criticism is not relevant to the facts. It is sufficient to point out some obvious differences between the two cases. We prove that vaccinia virus is being carried in a mouse tumour by showing that an extract of the tumour causes vaccinia; we cannot prove that the virus of the Rous sarcoma is present in the dibenzanthracene tumour by causing a Rous tumour with extracts: the extracts are completely harmless. The recognition of the supposed virus in the dibenzanthracene tumour is dependent on its resemblance to a tumour-producing virus. Further, when the dibenzanthracene tumour is artificially contaminated by the virus of the Rous tumour the contamination is recognizable by injecting chickens with a cell-free extract of the tumour, when a Rous sarcoma is produced. This fact, which we owe to Sir Edward Mellanby, pretty well disposes of the theoretical objection under discussion.

Rous's Work on the Shope Papilloma

We can now turn to the work of Peyton Rous on the Shope papilloma. This tumour was discovered by Dr. R. E. Shope on the skin of a cotton-tail rabbit. Shope found that the tumour is transmissible with filtrates and with glycerinated tissue both in cotton-tail and in domestic rabbits. The skin is shaved and then scarified as in vaccinating a person with calf lymph, and a filtrate or extract of glycerinated tissue is rubbed into the scarified area. After two to four weeks small translucent papillomas appear: they grow and eventually form large cauliflower-like masses of tissue. In cotton-tail rabbits the tumour can be transmitted in an endless series in this way, but in domestic rabbits, although the papilloma in them is larger and more fleshy as well as more aggressive in character, it has been found as a rule that transmission beyond the first generation is not possible. Thus the papilloma can be started in domestic rabbits, but thereafter the virus appears to be lost. Shope, however, has succeeded during the last few years in separating a strain of the virus which can, with some difficulty, infect domestic rabbits serially. There are now in most laboratories two strains—the "cotton-tail strain" and the "domestic rabbit strain."

The aggressive character of the papilloma in domestic rabbits, already referred to, is indicated by the frequency with which it becomes malignant. Experience in the laboratories of the Imperial Cancer Research Fund is that almost all Shope papillomas in domestic rabbits become malignant within two years. If the primary papilloma is very large malignancy may supervene within six months. In the cotton-tail rabbit, on the contrary, the papilloma rarely passes into carcinoma; Professor Berry of Rochester University has observed a case and Peyton Rous several out of hundreds of papillomas.

The position has thus been reached that a papilloma of the rabbit, caused by a virus, regularly passes into a state of malignancy. The carcinoma invades tissues locally and neighbouring lymph nodes and internal organs, especially the lung, leading to the death of the host animal. Is the virus the cause of the malignant growth also? If a cell-free filtrate of the growth would start a new malignant growth then the conclusion that the virus is the cause would be incontestable. But this is not so. Filtrates are completely inactive. It appears superficially that as soon as the papilloma becomes an invading true malignant neoplasm the virus disappears, and we are confronted with the same apparently insoluble problem presented by the generality of mammalian cancers.

succeeded also in proving that young males into which ovaries from litter-sisters were grafted may suffer from mammary carcinoma. It was concluded from these experiments that an ovarian hormone is in some way related to the occurrence of cancer of the breast. This conclusion was finally clinched by Lacassagne, who proved that the injection of folliculin in male mice of a cancer strain results invariably in cystic hyperplasia which passes into malignancy. These observations have been confirmed abundantly.

Oestrone, it should be noted, does not cause tumour formation at the site of application; it acts at a distance on an organ, the mamma, with which it is physiologically related. Its mode of action is being closely studied. My colleagues, Drs. Cramer and Horning, have already shown that under its influence complex changes occur in the ductless glands generally. The most conspicuous changes are in the adrenals and the pituitary body. In the adrenals brown degeneration in the zone between medulla and cortex takes place. The pituitary body, after an early period of hyperaemia, becomes greatly enlarged and congested, and frequently adenomas composed of chromophobe cells are found.

Cramer and Horning deduced from their studies of these phenomena that one or more of the hormones of the anterior lobe are capable of neutralizing the effects of oestrone on the pituitary gland. They proved by careful experiment that the thyrotropic hormone has this power. Injected weekly it keeps in check the mammary and pituitary changes produced by prolonged oestrinization, and in female mice having a high incidence of mammary cancer it prevents the spontaneous development of cancer of the breast.

The Proximate Cause of Cancer

It has already been pointed out that a tumour which has been started by applying one or other of many agents, chemical or physical in nature, may be propagable through an unlimited series of normal animals, and that the continued growth and multiplication of the malignant cells is independent of the action of the agents used in starting the tumour. How can we explain the change that has taken place within a cell when malignancy occurs? Verbal explanations are easy. It might be said that the cell has undergone "an irreversible change"; and doubtless a term of this kind, giving as it does an air of scientific validity, might prove satisfactory to chemists or physicists, who are accustomed to working with comparatively simple material under well-regulated conditions. But the explanation carries us no further. Similarly a solution of the problem might be conveyed by suggesting that the malignant cell is a somatic mutant. Such an explanation again is merely verbal. It has no factual basis, it ignores some well-established facts, it is arrived at by the dangerous process of reasoning by analogy, and it offers no prospect of further advances in knowledge. It is unprofitable to spend time in considering such explanations. I shall confine my attention to the view that a virus may be the proximate or intimate cause of malignant growths. The reason for doing this is that there are many tumours in which a virus cause has been established, and this fact gives a feeling of security that we are not living in regions of pure speculation.

Mode of Action of a Tumour Virus

First of all it must be made clear that the mode of action of a tumour virus is different from the action of carcinogenic agents. The virus acts promptly, is specific both to the animal and to the tissue, and can be recovered

again from the tumour which follows inoculation. With a filterable tumour like the Rous sarcoma No. 1 or the Imperial Cancer Research Fund's strain of endothelioma known as Mill Hill No. 2, tumour formation begins in a week or less after inoculation; each virus produces only its own tumour in only one species of animal; and the virus increases in amount with the growth of the tumour. When a tumour is started with the most active of carcinogenic agents—with benzpyrene, for example—the story is quite different. In the first place, the time interval between application of the chemical substance and the appearance of a tumour is, even in the most sensitive animals, a matter of months. In the second place, the kind of tumour produced depends upon the site of application: if the skin is painted a squamous carcinoma results, but if the substance is injected into the subcutaneous tissues a sarcoma follows. There is no specificity of action. And, in the third place, the chemical substance, though present in the primary tumour, is not necessary to the growth of the tumour and is not recoverable from remote generations of transplants. It is puzzling to understand how it comes about that viruses are so often classed with the carcinogenic agents when their mode of action is so manifestly different.

I must now hasten to state that the tumours for which a virus cause has been established are comparatively few in number; or, rather, are almost confined to birds. They consist of tumours of the domestic fowl, a rabbit papilloma which goes on to malignancy, and an adenocarcinoma of the kidney of a certain species of frog. Other tumours may assume a filterable phase, as Parsons has shown for a mouse sarcoma which had been induced by injections of a complex hydrocarbon. The great majority of tumours used in experimental research—tumours of mice, rats, guinea-pigs, dogs, etc.—can be propagated only with living cells. If attention is restricted to these it must be observed that nothing could appear more improbable than the notion that these tumours are caused by an intracellular virus. They give no evidence of any sort that a virus is at work. It is largely because of this that the majority of pathologists have until recently paid scant attention to viruses in cancer. At present, it is fair to remark, most workers in cancer would agree that any coherent explanation of cancer must include an explanation of the filterable tumours.

The division of tumours into two kinds—those which can and those which cannot be transmitted by cell-free extracts—is one of the major puzzles of experimental cancer research. Why some tumours readily yield an infective agent and others subjected to the same treatment should give innocuous extracts is at present inexplicable. But recent work has shown that failure to demonstrate an intracellular causative agent by direct means—that is, by serial transmission of tumours with non-cellular material—must not be interpreted too dogmatically. This conclusion is supported by two pieces of research—one by Foulds, who worked with a dibenzanthracene tumour of a fowl, and the second Peyton Rous's revolutionary work with the Shope papilloma.

Foulds's Work with Non-Filterable Dibenzanthracene Tumours

The tumour studied by Foulds is a fibrosarcoma of the domestic fowl. It was brought into existence by injecting a hen with a solution of dibenzanthracene in lard.* The original purpose of inducing a tumour in this way was to determine whether an artificially induced tumour is trans-

* The dibenzanthracene was generously provided by Professor Kennaway.

vitamin C metabolism in a series of patients with gastro-intestinal ulceration, and these form the basis of the present report.

Test Subjects and Patients

The 107 subjects employed in these tests are divided quite easily into four distinct groups:

Group I.—A control group consisting of twenty-six members of the departmental staff and medical students; all gave excellent dietary histories, including a good supply of vitamin-C-containing foods.

FIG. 1.—Showing daily excretion of ascorbic acid in normal controls and patients with peptic ulcers with and without haematemesis.

Group II.—A control group consisting of twenty-five miscellaneous patients chosen at random from the Infirmary wards, excluding those with gastric or renal disease; these were taking standard hospital diets and gave dietary histories varying from "good" to "poor," the greater number being in the "good" category.

Group III.—In this group were twenty-five patients suffering from proved peptic ulceration but without haematemesis, and they were all receiving special diets of the Hurst No. 1 and No. 2 types, or modifications of them.

Group IV.—This group contained thirty-one patients who were admitted to hospital on account of severe haematemesis—attributed to peptic ulceration. They had all been on very poor diets, and were put on special diets (mostly of the Hurst No. 1 type) on admission to hospital.

Methods of Investigation

Six methods were used for the determination of vitamin C deficiency in these subjects; they are considered under their respective headings: (1) the daily urinary excretion of ascorbic acid; (2) the ascorbic acid "saturation" test; (3) plasma ascorbic acid determinations; (4) oral ascorbic acid tolerance tests; (5) intravenous ascorbic acid tolerance tests; and (6) the intradermal test.

Technique and Results

1. THE URINARY EXCRETION OF ASCORBIC ACID

This was carried out by the method of Harris, Ray, and Ward (1933), which is a modification of Tillmann's 2:6-dichlorophenolindophenol method, the urine being collected every twelve hours and titrated against the dye. The special precautions for collecting, storing, and titrating the urine were rigidly observed. The minimal normal amount of ascorbic acid excreted in twenty-four hours as determined by this method is about 13 mg., and this figure has been adopted here. (Harris *et al.*, 1936.)

The control subjects in Group I all excreted more than the minimal normal daily amount of 13 mg. of ascorbic acid (22 to 39 mg.), the mean daily excretion being 29 mg. In nineteen patients (76 per cent.) of the second group of twenty-five control patients who had been selected at random, similar

daily excretions were obtained, while the remaining six patients (24 per cent.) in this group who gave poor dietary histories excreted less than 13 mg. daily; the mean daily excretion for the whole of Group II was 17 mg. (7 to 35 mg.). All the patients in Group III excreted less than 13 mg. ascorbic acid daily, with a mean of 7 mg. and a range of 5 to 11 mg.; similar values (mean 7 mg., range 5 to 10 mg.) were obtained with the patients in Group IV. (See Fig. 1.)

2. THE ASCORBIC ACID "SATURATION" TEST

This test is a modification of that described by Abbasy *et al.* (1935). The average daily excretion of ascorbic acid was determined over a period of about six days; at the end of this

period a dose of ascorbic acid (500 to 1,000 mg.) was given orally, and the amount excreted in the urine in the subsequent twenty-four hours was estimated as in the first method. If the urinary concentration of ascorbic acid did not show any increase following this dose the latter was repeated until "saturation" was reached.

Most of this test dose of ascorbic acid is retained by the body stores in a deficient patient, and in many cases there is no increase in the initially low urinary excretion; in a "saturated" patient, however, a large percentage of the administered ascorbic acid is excreted, the well-filled body reserves being able to dispense with the surplus. Since several different standards have been employed by other workers we have taken an excretion of 50 per cent. of an oral test dose as evidence of "saturation." The types of result so obtained are shown in Fig. 2 where it will be seen that, in contrast with

FIG. 2.—Illustrating the difference in dosage of ascorbic acid required to saturate individuals taking normal and ulcer diets. The oral administration of 500 mg. of ascorbic acid is indicated by an arrow.

the normal patient (J. N.), who required 1,000 mg. much larger quantities (4,500 mg.) of ascorbic acid were necessary to produce "saturation" in patient F. H., who took nine days before saturation occurred, while receiving 500 mg. ascorbic acid daily.

Again we have to seek indirect evidence. Peyton Rous succeeded in propagating the carcinoma through two generations of rabbits by the process of grafting fragments of living carcinoma cells taken, in order to avoid the possibility of including papilloma cells in the inoculum, from an "infected" lymph node. As the implanted cells grew to form "daughter tumours" it was found that the blood serum of the rabbits acquired an immune body which neutralizes the papilloma virus. The conclusion which must be drawn from these observations is that, although filtration experiments with the carcinoma give negative results, the carcinoma cells do nevertheless carry the papilloma virus. The final proof that the virus acts causatively is more difficult, though it is fair to observe here that if we were now discussing any other subject than cancer the *prima facie* evidence that the virus is acting as the cause of the pathological condition under investigation would be scarcely questioned. At least it may be said that the negative filtration results do not warrant the conclusion that the papilloma virus is absent. It is very probable, indeed almost certain, that conditions exist within the cells of the tumour under which a virus-protoplasm complex is formed and that filterability may depend upon an easy or a particular dissociation of the complex.

Relation Between Carcinogenic Agents and Viruses

Passing now to the relation between the action of carcinogenic agents and viruses, it is necessary to discuss an experiment with coal tar and papilloma virus carried out by Peyton Rous. When coal tar is applied once a week to the skin of a rabbit's ear papillomas form after a few months, the time depending upon the quality of the tar. Some of the papillomas may, after a much longer time—a year or more—become malignant. The experiment carried out by Rous was as follows:

A series of rabbits were painted with coal tar for about three months, when small papilloma began to appear. Some of the rabbits then received intravenously an injection of virus obtained from a papilloma of the cotton-tail rabbit. Painting the ears with tar was continued on all the rabbits, control and experimental alike. After two to three weeks—the incubation period usually observed with the virus in its action on the skin—the tarred areas in those rabbits which had received virus developed true anaplastic rapidly growing squamous carcinomas. The cancers appeared both at the sites of papilloma formation and on tarred areas devoid of papillomas. No cancers appeared on areas that had not been tarred. The control rabbits, which had been treated with tar only, showed no cancer at the time nor later, a long while after the others had died of generalized cancer.

This experiment has been repeated and confirmed, and has excited world-wide interest. Like so much work of Peyton Rous it goes to the heart of the problem. It will doubtless be subjected to criticisms similar to those already discussed in dealing with Foulds's work with non-filterable dibenzanthracene tumours—namely, that it is possible to cause viruses of all sorts to lodge in tumour growths. But these criticisms are invalid; for, as Rous himself has pointed out, when a virus such as Virus III is carried as a contaminant in a transplantable rabbit carcinoma the virus has no effect on the tumour, whereas in his experiment the Shope virus causes quickly a definite specific change in the tar lesion, and the change corresponds with changes which it is known that the virus may induce slowly under normal and presumably less favourable conditions. It is more reasonable to look upon the action of tar as being of a preparatory kind, as affecting the cells in such a way as to render them very susceptible to the action of the virus. If this view is correct—and it certainly is in conformity with the fact that carcinogenic

agents like tar have a fundamentally different mode of action from that of a virus—it permits us to postulate as a working hypothesis that when a tumour is induced in an animal by applying carcinogenic agents the vital change from hyperplasia to malignancy is probably associated with the entry of a virus. This presupposes the widespread existence within the animal body of viruses of low infectivity but capable, when suitably conditioned, of entering cells and setting in motion the train of events described as cancer. Some difficulty is felt in accepting the supposition, but it can be pointed out that where it is possible to make experiments capable of yielding information some supporting evidence has been found. Thus it is now known, following the first observations by Pentimalli, that immune bodies which neutralize the viruses of avian neoplasms appear in the blood in a high percentage of apparently normal fowls more than 18 months old. These immune bodies are presumably formed in response to a virus related to or identical with the viruses found in actual neoplasms.

An outline of cancer work in progress must necessarily be incomplete; each section could be expanded into several lectures. But I hope I have given evidence that progress is being made in many directions and that what has been done already justifies us in our optimism.

VITAMIN C DEFICIENCY IN PEPTIC ULCERATION AND HAEMATEMESIS

Physician in Charge and Director of the Department of Clinical Investigations and Research, University and Royal Infirmary, Manchester; Honorary Consulting Haematologist, Christie Cancer Hospital and Holt Radium Institute

Although frank clinical scurvy rarely follows the modern conservative methods of dietetic treatment of peptic ulceration (Davidson, 1928; Barling, 1935; Wood, 1935; Platt, 1936) it is now being realized that early "pre-scorbutic" or "subclinical" states may occur quite frequently. The experimental evidence put forward by McCarrison (1919, 1931), Magee *et al.* (1929), McConkey (1933), and Smith (1933) shows that ulceration of the stomach and duodenum is very apt to occur in animals in a state of vitamin C deficiency, while the importance of vitamin C in the normal reparative processes has been further emphasized quite recently by Lanman and Ingalls (1937), who have shown that a deficiency of this vitamin is a potent factor in delayed wound healing.

Harris *et al.* (1936) found that nineteen patients with peptic ulcers had distinctly subnormal daily urinary excretions of ascorbic acid, but in that particular inquiry 84 per cent. of all the patients examined showed subnormal daily urinary excretion values. An important contribution was that of Archer and Graham (1936), who showed that six out of nine patients with peptic ulcers, for which they were receiving dietetic treatment, were in the "subscorbutic" state. In the course of our investigations we have had the opportunity of examining the

Simultaneously with these blood changes it was noticed that the urinary concentration of ascorbic acid showed an increase maximal at four to six hours and an increase in the total amount excreted in the urine at that time. During the entire twenty-four hours from the beginning of the test approximately 500 mg. (50 per cent. of the test dose) of ascorbic acid was excreted in the urine.

When, however, we turn to Groups III and IV very different results were noticed. Here also the two groups of patients can be considered together, owing to the similarity in plasma ascorbic acid titres. The low initial ascorbic acid values (Group III below 0.41 mg. and Group IV below 0.34 mg. per 100 c.c.m.) showed very slight alterations, increasing only to 0.48 to 0.60 mg. per 100 c.c.m. in one to two hours after the test dose. The urinary concentration during this test showed little or no increase, and in the subsequent twenty-four hours the excretion of ascorbic acid was much less than 500 mg., while quite often no increase at all was noted, even in the total twenty-four-hour specimen. (See Fig. 3.)

While these oral tolerance curves give accurate results the criticism might be made that variation in absorption from the gastro-intestinal tract, together with other factors causing destruction of the vitamin there, might affect the results; the same criticism could be made of the "saturation" test. To eliminate this possibility an intravenous method of applying the ascorbic acid tolerance test was introduced.

5. THE INTRAVENOUS ASCORBIC ACID TOLERANCE TEST

This consists in estimating the rise in plasma ascorbic acid after the administration of ascorbic acid intravenously, as follows:

The day preceding the test a control experiment is carried out as in the oral tolerance test. At 9 a.m. on the following day a sample of blood is taken as before, and then 1,000 mg. of ascorbic acid are given intravenously in the form of redoxon forte (10 c.c.m. = 1,000 mg.). As our experiments showed that the plasma ascorbic acid begins to rise very rapidly after the injection, the next specimen of blood is taken fifteen to twenty minutes later (it was convenient in this series to take the first sample at eighteen minutes), and then further venous blood samples at hourly intervals after the injection of ascorbic acid for a period of five hours, the plasma ascorbic acid being determined in each. The urine is collected hourly and titrated immediately, as in the oral tolerance test above.

In the normal group of subjects the plasma ascorbic acid rises to very high levels in the first fifteen to twenty minutes, but in the deficient group the rise is not so marked (typical results are seen in Fig. 4 and Table I). The urinary concen-

TABLE I.—*Intravenous Tolerance Tests. Showing the Results Obtained in Patients with the Highest, Middle, and Lowest Initial Plasma Ascorbic Acid Values in Groups I and II, III and IV*

		Ascorbic Acid, mg. per 100 c.c.m. Plasma after Injection of 1,000 mg. Ascorbic Acid Intravenously						
		0 hr.	15 min.	1 hr.	2 hrs.	3 hrs.	4 hrs.	5 hrs.
Groups I and II	Highest	1.85	11.40	6.94	4.00	2.21	1.34	1.35
	Middle	1.21	9.40	6.00	2.99	1.78	1.45	1.24
	Lowest	0.70	6.60	2.34	1.74	1.10	0.70	0.72
	Mean	1.20	10.12	5.62	2.76	1.63	1.55	1.22
Groups III and IV	Highest	0.59	6.90	2.66	—	0.93	0.63	0.60
	Middle	0.38	5.64	1.99	1.10	0.81	—	0.48
	Lowest	0.14	2.89	1.09	0.63	0.42	0.31	0.29
	Mean	0.36	4.45	1.69	1.05	0.76	0.51	0.42

tration of the ascorbic acid increases rapidly to higher levels in the normal than in the deficient group, and is usually maximal at the end of one to two hours.

We find that it is better to take account of the amount excreted in the six hours following injection of the test dose rather than the concentration, since from previous experiments at least 500 mg. of the 1,000 mg. test dose was excreted in the urine in the subsequent twenty-four hours in normal

controls, and approximately 80 per cent. of this twenty-four-hour ascorbic acid excretion—that is, 400 mg.—was excreted in the first five to six hours following the intravenous administration of the test dose. These urinary excretions are illustrated in Fig. 5. It thus appears probable that the amount excreted in the first five to six hours after the injection may be an accurate index of the body saturation with respect to vitamin C. (While these experiments were in progress our views were confirmed in a valuable paper by Wright, Lilienfeld, and McLenathan (1937), using a similar method.)

In our control groups (I and II) the results were very similar, and can be classified together as in the case of the

FIG. 5.—Showing amount of ascorbic acid excreted following a single intravenous dose of 1,000 mg. ascorbic acid. Each column represents the amount excreted in the twenty-four hours, and the unshaded portion shows the amount excreted in the first five hours.

oral tolerance curves. The initially high plasma ascorbic acid values (0.70 to 1.41 mg. per 100 c.c.m. in this test) rose very rapidly to maxima of 6.6 to 11.4 mg. per 100 c.c.m. in the fifteen to twenty minutes after the intravenous administration of the 1,000 mg. test dose of ascorbic acid: this was followed by a progressive fall during the subsequent five to six hours to the initial blood level. In the twenty-four hours after the injection not less than 660 mg. (660 to 985 mg.) of the 1,000 mg. test dose of ascorbic acid was excreted in the urine, and at least 500 mg. (549.3 to 934 mg.) was excreted in the first five hours following the injection, representing 83 to 95 per cent. of the total amount excreted. (See Figs. 4 and 5 and Table II.) Slightly less ascorbic acid was excreted in the urine in the full twenty-four hours in Group II patients than in those of Group I.

In the two groups of ulcer patients with and without haematemesis (Groups III and IV) this intravenous tolerance test gave results which can also be conveniently considered together. The low initial plasma ascorbic acid values (0.14 to 0.59 mg. per 100 c.c.m.) rose in the first fifteen to twenty minutes after the injection to values of 2.00 to 7.01 mg. per 100 c.c.m., but on the whole the lower values were noted in the group of patients with haematemesis. In contrast to Groups I and II the amount of ascorbic acid excreted in the urine by these patients in the twenty-four hours was well below 500 mg. (72 to 458 mg.), although, as before, at least 80 per cent. (64 to 418 mg.) of the total excretion in twenty-four hours was excreted in the five hours immediately after injection (Table II). Thus from our results it is clear that a good estimation of the vitamin C nutrition of the body can be obtained by estimating the amount of ascorbic acid excreted in the urine in the first five hours after injection, since at least 80 per cent. of the twenty-four-hourly amount is excreted in that time. Apart from eliminating alterations of the vitamin in the alimentary tract this method is particularly suitable for hospital use, where the daily collection of urine entails considerable work for the nursing staff.

6. INTRADERMAL TEST

In April, 1937, Rotter suggested a test for vitamin C deficiency which depended upon an observation that a solution

Using this method we find that test doses of 500 to 1,000 mg. of ascorbic acid produce saturation in the Group I controls, while 700 to 2,300 mg. (mean 1,252 mg.) were given before saturation was reached in Group II control patients. On the other hand, in the ulcer patients under examination 2,100 to 5,000 mg. (mean 3,691 mg.) of ascorbic acid were given in Group III and totals of 2,000 to 8,000 mg. (mean 4,543 mg.) in Group IV before "saturation" was reached, figures greatly in excess of the average values required in the two control groups (see Table III).

3. PLASMA ASCORBIC ACID DETERMINATIONS

The blood contains ascorbic acid in the reduced and the oxidized forms, the greatest amount occurring in the reduced form. This reduced ascorbic acid content of plasma can readily be determined by Pijoan and Klemperer's modification (1937) of the method of Farmer and Abt (1935); values between 0.66 and 2 mg. reduced ascorbic acid per 100 c.cm. plasma are regarded by these workers as normal, and closely coincide with our own findings. The total ascorbic acid content of blood can be determined by the method of Mirsky *et al.* (1935), and these values have also been determined in our cases. From our own experience and that of Farmer and Abt we believe the reduced ascorbic acid content of plasma to be much more important and accurate than the total ascorbic acid in assessing the state of the body with regard to vitamin C. Since the total blood ascorbic acid values add nothing to the present discussion we propose to omit them from this paper. In individuals on a good vitamin-C-containing diet we found the plasma ascorbic acid lay between 0.60 and 1.85 mg. per 100 c.cm. In the patients of Groups III and IV values between 0.14 and 0.59 mg. per 100 c.cm. were obtained, and in Group IV the mean (0.34 mg. per 100 c.cm.) was lower than that of Group III (0.42 mg. per 100 c.cm.).

It must be remembered that while the reduced ascorbic acid content of plasma gives at a single estimation a fair index of the state of the tissues in relation to vitamin C, yet it is subject to fairly rapid fluctuations, and a subnormal plasma ascorbic acid may occasionally be found although no gross deficiency can be proved by other tests. A case illustrative of this was that of a patient with a plasma ascorbic acid content of 0.54 mg. per 100 c.cm. who required only the comparatively small dose of 1,000 mg. ascorbic acid orally before "saturation" occurred. This finding of a low plasma ascorbic acid in spite of adequate reserves is explained by the fact that the plasma ascorbic acid falls rapidly in a few days on a vitamin-C-deficient diet, although there will not be as yet any marked

decrease in the tissue content of ascorbic acid. On the other hand, the finding of a normal or high plasma ascorbic acid shows the patient to have good reserves of the vitamin (always assuming that a large dose of vitamin-C-containing food has not been taken before the test begins), and a single estimation should be sufficient without corroborative evidence from other tests.

It should be mentioned that we find the plasma ascorbic acid to be very constant from hour to hour on a non-supplemented diet. We also find that in the normal patient taking an adequate supply of vitamin C in the diet there is very little variation in plasma ascorbic acid from day to day.

4. THE ORAL ASCORBIC ACID TOLERANCE TEST

We investigated the possibility of using the changes in the plasma ascorbic acid after an oral test dose of ascorbic acid as a means of detecting vitamin C deficiency. This "oral ascorbic acid tolerance test," as we have called it, is carried out in the following manner:

The patient is not given any extra vitamin-C-containing foods, other than the ordinary hospital diet, on the day before the test. Five c.cm. (10 c.cm. if the total ascorbic acid is also to be estimated) of blood are withdrawn from a convenient vein at hourly intervals for four hours, and the reduced ascorbic acid value of the plasma is determined. This preliminary test acts as a control to show the constancy of the blood ascorbic acid level on a non-supplemented normal diet. At 9 a.m. the following day the ascorbic acid content of the blood is again determined and 1,000 mg. of ascorbic acid administered orally in the form of twenty redoxon tablets (one tablet equals 50 mg.); 5 or 10 c.cm. of venous blood are then taken every hour for five hours and the blood ascorbic acid values redetermined. The patient is instructed to void urine as nearly as possible at each hourly interval; such sample being titrated at once.

FIG. 3.—Plasma ascorbic acid tolerance tests, showing effect of 1,000 mg. ascorbic acid given orally to normal controls and patients with peptic ulceration; the corresponding mean urinary values are also shown.

FIG. 4.—Plasma ascorbic acid tolerance tests, showing effect of 1,000 mg. ascorbic acid given intravenously to normal controls and patients with peptic ulceration.

In Fig. 3 typical curves for the highest and lowest limits are shown to illustrate (a) normal controls on diets containing an adequate amount of vitamin C, and (b) patients on vitamin-C-deficient diets (for example, Hurst No. 1 ulcer diet).

Using the oral method as described above, the controls of Groups I and II had initial plasma ascorbic values above 0.80 mg. per 100 c.cm. Apart from slight initial differences, which were within the normal limits, the results were practically identical in Groups I and II, and they therefore may conveniently be considered together. After the administration of the test dose of 1,000 mg. of ascorbic acid orally, the plasma ascorbic acid values in both groups showed rapid increases in the first two hours to peaks of 1.80 to 3.50 mg. per 100 c.cm., followed by returns to the initial plasma levels at the end of five to six hours.

that normal unsaturated controls may require fairly large quantities of ascorbic acid for "saturation," we suggest that the comparative value of the results loses nothing in value, since, as will be seen from our results, there is such a big difference between the amounts of ascorbic acid required to "saturate" normal controls (Groups I and II) and test patients (Groups III and IV). While this may not be of absolute significance its comparative importance cannot be overlooked.

It must be remembered that before ascorbic acid can be excreted in the urine absorption must take place in the alimentary tract, and pathological changes therein—for example, inflammatory conditions—may well affect the absorption of the vitamin, while alterations in the alimentary chemistry and physics may also lead to destruction of ascorbic acid. The ulcer patients in Groups III and IV as a routine measure were given alkalis, and since ascorbic acid is destroyed rapidly in alkaline solutions there may be much less in the stomach and upper intestine before absorption (further work on this point is already in progress): the occurrence of an alkaline urine, part of which may be in the bladder overnight, leads to lower values for urinary ascorbic acid than are found with an acid one (Hawley *et al.*, 1936).

The determination of the ascorbic acid content of the plasma thus serves as a very useful guide, and it is probable that this will ultimately prove to be a more reliable diagnostic test in the detection of vitamin C deficiency. It must be borne in mind, however, that the normal resting plasma ascorbic acid (0.6 to 1.85 mg. per 100 c.cm.) is subject to sudden fluctuations after a temporary deficiency of the vitamin in the diet: in these circumstances a low plasma ascorbic acid may be obtained, but if the figure falls much below 0.45 mg. per 100 c.cm. dangerous depletion of the body stores of the vitamin is developing. The highest figure obtained in Groups III and IV—patients with peptic ulceration with and without haematemesis—was 0.59 mg. per 100 c.cm., and the lowest 0.14 mg. per 100 c.cm., the lowest values and the severest degree of deficiency tending to be found in the patients with haematemesis (Group IV).

The responses following oral-test doses of ascorbic acid show considerable differences between the plasma ascorbic acid levels in the control subjects and those in the patients with peptic ulcer; in the latter they are almost negligible. Similarly the urinary concentration of ascorbic acid in the following four to six hours shows little or no increase in the ulcer patients, although good responses are obtained in the controls. In this test, however, both plasma and urinary changes are dependent upon the rate of absorption of ascorbic acid from the alimentary tract, and therefore the criticism applied to the saturation test may also apply to this one. The intravenous method of administering the ascorbic acid overcomes this objection; nevertheless the rapid increase of plasma ascorbic acid that occurs in fifteen to twenty minutes after intravenous administration of the test dose is still very different in the control groups (I and II) and in the patients with peptic ulceration, the responses in the latter being very much smaller.

Perhaps of rather more importance is the fact that in our normal controls 660 to 935 mg. of the test dose are excreted in the urine in the subsequent twenty-four hours, while only 72 to 458 mg. are excreted in the "ulcer" patients; further, the greater part (at least 83 per cent.) of the ascorbic acid excreted in twenty-four hours appears in the first five hours after injection and thus offers the possibility of greatly simplifying the test, so that it is only necessary to determine the first five hours' excretion following intravenous injection of 1,000 mg. ascorbic acid.

Values below 400 mg.—that is, 80 per cent. of 500 mg., the minimal twenty-four hours' excretion—are regarded as subnormal. Thus in five hours an accurate estimation is obtained of the vitamin C content of the body. In this manner it is possible to avoid alteration of the vitamin in, or differences in the rate of absorption from, the alimentary tract, and it also avoids almost entirely the loss of ascorbic acid in the bladder in the presence of an alkaline urine overnight. The intradermal test is regarded as only a rough index of vitamin C deficiency; nevertheless for rapid clinical use where elaborate facilities are not available it may well prove useful.

It will be noted that all the methods used compared well with one another, and it has been shown that, taking the level of normal controls on good dietary intakes of vitamin C as a standard, there is a marked deficiency of vitamin C in patients with peptic ulceration and haematemesis.

In spite of the experimental evidence put forward from animal experiments it cannot be suggested that lack of vitamin C is an aetiological factor in production of peptic ulceration or haematemesis, although it may well be concerned in delayed healing or the chronicity of peptic ulcers. The diet should therefore be corrected by the addition of the vitamin so that the needs of the body as a whole be not overlooked. The diet used in the treatment of peptic ulceration, especially after haematemesis, will rapidly produce a vitamin C deficiency and a vicious circle thus be set up, leading to delayed healing of the ulcer.

It is interesting to note that the patients with haematemesis showed the greatest deficiency of the vitamin, since it has long been recognized that a sufficiently severe C avitaminosis is associated with increased capillary fragility—in fact, the original tests for vitamin C deficiency were based on this fact (Gothlin, 1931). It is clear, therefore, in view of our results and those of other workers, that the diet of these patients with gastric or duodenal ulceration and haematemesis should be amplified by the addition of vitamin C, while the parenteral administration of ascorbic acid in the first few days should be of considerable value in reaching a rapid saturation of the tissues.

Summary

1. The blood content and the urinary excretion of vitamin C (ascorbic acid) have been investigated by six methods in a series of 107 subjects (fifty-one control subjects, twenty-five patients with peptic ulceration, and thirty-one patients with haematemesis).

2. Using the urinary excretion method, groups of normal controls, miscellaneous ward controls, patients with peptic ulcers, and patients with haematemesis excreted mean amounts of 29, 17, 7, and 7 mg. respectively daily.

3. With the saturation test it was found that to produce a 50 per cent. excretion of the administered ascorbic acid the normal controls, patients with peptic ulceration, and patients with haematemesis required 500 to 2,300, 2,100 to 5,000, and 2,000 to 8,000 mg. respectively.

4. The initial plasma ascorbic acid value (normal 0.60 to 1.85 mg. per 100 c.cm., patients with peptic ulceration and haematemesis 0.14 to 0.59 mg. per 100 c.cm.) was an approximate measure of the vitamin C nutrition of the body tissues.

5. An oral ascorbic acid tolerance test has been described after oral administration of 1,000 mg. ascorbic acid; the maximal plasma ascorbic acid value was reached in one to two hours, while the maximal urinary excretion occurred in four to six hours; in normal controls there was a good response in both blood and urinary levels—in

of 2:6-dichlorophenolindophenol, when introduced intradermally, is decolorized at a speed dependent upon the degree of vitamin C saturation of the tissues. We therefore compared this intradermal test with the results obtained with the five methods described above in a series of 103 patients, and have already published our technique and results (Portnoy and Wilkinson, 1938). From the preliminary figures it appears that individuals who are on a "good" diet with regard to the vitamin give decolorization times of less than ten minutes, while those taking large amounts of vitamin C in their food give decolorization times below five minutes. On the other hand, prolongation of the decolorization time over ten minutes is suggestive of a lack of vitamin C in the tissues.

TABLE III

	Groups of Controls and Patients			
	I	II	III	IV
Excretion of ascorbic acid in 24 hours before saturation. Mg.(mean)	29	19	7	7
Ascorbic acid (mg.) given before saturation produced ..	684 (500-1,000)	1,251 (700-2,300)	3,691 (2,100-5,000)	4,543 (2,000-8,000)
Reduced ascorbic acid in blood (mg. per 100 c.cm.): Means—				
Before saturation	1.28	0.80	0.42	0.34
After saturation ..	1.71	1.50	1.39	1.55
Oral tolerance test ..	Not deficient	Not deficient	Deficient	Deficient
Intravenous tolerance test ..	Not deficient	Not deficient	Deficient	Deficient
Intradermal test: mean decolorization times (minutes) ..	6.3		16.9	

Taking the control subjects of Groups I and II together we found the mean decolorization time to be 6.3 minutes (3 to 11 minutes), while the patients in Groups III and IV together gave a mean decolorization time of 16.9 minutes (3 to 29 minutes). However, after saturation (as shown by the methods described above) of these patients in Groups III and IV all the decolorization times were between 0.5 and 6 minutes.

Discussion

By employing the different methods for the determination of vitamin C we have been able to compare their results and to use them in estimating the degree of "saturation" of the body in respect to vitamin C in groups of normal subjects and of patients with peptic ulceration and with haematemesis. The measurement of the daily urinary excretion of ascorbic acid is said to be a fair index of deficiency, a value of about 13 mg. being taken as the average minimal excretion. Low excretion figures were in this way obtained by Harris and Ray (1935) in scorbutic infants; on the other hand, in Schultzer's (1936) series of scorbutic patients the excretions during each twenty-four hours of the control period before performing the "saturation" test were 13, 19, and 24 mg. respectively, although large quantities of ascorbic acid (9,500, 7,000, and 14,400 mg.) were required for "saturation." In our Groups III and IV it will be seen that all the patients gave figures below 13 mg., although the control groups gave higher values in all but six patients.

The "saturation" test has been employed quite frequently, and also appears to furnish a fair index of vitamin C saturation of the tissues; we consider it to be more accurate than the estimation of daily ascorbic acid excretion in the urine. The term "saturation" as introduced by van Eekelen *et al.* (1933) and Johnson and Zilva (1934) is a state of optimal ascorbic acid supply above which excess of ascorbic acid is excreted almost quantitatively (70 to 80 per cent.) in the urine within eight hours of ingestion. Nevertheless "unsaturation" is not an abnormal state and occurs in normal individuals, who, Johnson and Zilva (1934) have shown, may require 200-mg. doses of ascorbic acid for several days before an increase in the urinary output is noted. Unless the individual remains on a diet containing excess of vitamin C this state of "saturation" is not maintained, and the individual becomes rapidly "unsaturated," though normal. However, while agreeing with these workers on the fact

the vitamin deficiency in question preceded the development of peptic ulcer or was a result of the therapeutic regimen.

Method

The method adopted was similar to that described by Göthlin (1931) and used by him and his collaborators (Falk, Gedda, and Göthlin, 1932) in the investigation of a large number of normal and pathological subjects. The principle of the test is to compress the upper arm at standard pressure so as to increase the pressure within the capillaries, and then to count the number of ruptured capillaries after a given time as shown by the number of petechiae visible within a given area of skin. As a rule three subjects were tested simultaneously. A central compression chamber was used, to which were connected a metal compressor, a mercury manometer, and three rubber tubes leading to three standard blood-pressure tourniquets. It was found possible to make this system sufficiently airtight to dispense with the fine adjustment mechanism used by Göthlin. A circle of 60 mm. diameter was marked out in the angle of the elbow by means of a standard rubber stamp. The petechiae occurring within this area following the compression of the upper arm at a standard pressure (50 mm. Hg) were counted and the number recorded. The following information was obtained in respect of each patient: the disease and its duration, length of stay in hospital up to the time of the test, diet while in hospital, diet during the two months immediately preceding entry into the hospital, and diet before the appearance of any symptoms of the disease.

Results of the Investigation

Eighty-seven subjects in all were examined by Göthlin's method. Of these, twenty-eight were suffering from gastric ulcer, fourteen from duodenal ulcer, and twenty-three from various diseases other than peptic ulcer, while twenty-two were normal healthy persons living an ordinary life with free choice of diet and sufficient private means to purchase ample fruit and vegetables.

THE NORMALS

The following results were obtained from the normals:

8 gave no petechiae	2 gave 4 petechiae
4 " 1 petechia	1 " 6 "
5 " 2 petechiae	1 " 9 "
1 " 3 "	

Total: 22 patients gave 40 petechiae.
Average number of petechiae, 1.82.

Göthlin gives 0 to 4 as the normal range of petechiae, 5 to 8 as indicating a transitional stage of vitamin C deficiency, and more than eight as showing a definite deficiency. There was no particular evidence of vitamin C deficiency in the diet of the two normals giving more than four petechiae, so we may class these as being in the nature of sporadic variations from the normal.

THE GASTRIC ULCER CASES

The twenty-eight patients suffering from gastric ulcer gave the following results:

1 gave no petechiae	3 gave 8 petechiae
1 " 1 petechia	2 " 9 "
1 " 2 petechiae	1 " 10 "
3 " 3 "	2 " 13 "
6 " 5 "	1 " 14 "
3 " 6 "	1 " 26 "
3 " 7 "	

Total: 23 patients gave 199 petechiae.
Average number of petechiae, 7.10.

Statistical analysis shows that this mean is significantly different from that found above for normals.

From these results it may be seen that if we accept Göthlin's standards 53.6 per cent. of the patients were in a transitional stage of vitamin C deficiency and 25 per cent. were showing definite signs of deficiency. Actually the deficiency demonstrated by these results is greater than it appears, for some of the patients giving a small number of petechiae were receiving dietary supplements containing vitamin C, such as orange juice. This applies, for example, to the first two on the list, and if these are excluded the average number of petechiae then becomes 7.61 instead of 7.10.

The diet prescribed for patients in hospital was a modified Sippy diet, including the administration of alkalis. All of those patients who developed fewer than four petechiae had received supplementary sources of antiscorbutic vitamins, such as orange juice, in addition to the usual gastric ulcer diet. In the case of those patients developing four or more petechiae the only source of antiscorbutic vitamins was small quantities of potato, and the longer the patient's stay in hospital on this regimen the greater was the number of petechiae which developed. It therefore appears that the degree of fragility of the capillaries can be correlated with an inadequate intake of antiscorbutic vitamins. The records further show that, at least in some patients, the ulcer had developed in spite of an apparently ample supply of antiscorbutic vitamins in the diet before the patient came under treatment. There was therefore no definite evidence that lack of antiscorbutic vitamins was directly responsible for the occurrence of ulceration.

THE DUODENAL ULCER CASES

Fourteen cases of duodenal ulcer gave the following result:

2 gave 1 petechia	1 gave 8 petechiae
2 " 2 petechiae	1 " 11 "
2 " 3 "	1 " 14 "
2 " 4 "	1 " 15 "
1 " 5 "	1 " 30 "

Total: 14 patients gave 103 petechiae.
Average number of petechiae, 7.36.

This figure again differs significantly from that obtained for normals. Twenty-eight and a half per cent. gave more than eight petechiae, and were therefore, according to Göthlin's standard, suffering from definite vitamin C subnutrition.

Those patients who developed fewer than four petechiae had, with one exception (in which orange juice had been added to the diet), obtained their antiscorbutic vitamins almost entirely from potatoes. Of those patients who developed four or more petechiae none had received any important source of antiscorbutic vitamins in the diet for at least two weeks before the test. One possible exception to this was the patient who developed thirty petechiae, whose only source of antiscorbutic vitamins for some months had been boiled turnips. As in the case of gastric ulcer patients, therefore, the degree of capillary fragility could be correlated with the deficiency of antiscorbutic vitamins in the diet. Potatoes, however, seemed to be more effective in supplying enough antiscorbutic vitamins to prevent capillary fragility than in cases of gastric ulcer. There also appeared to be considerable variation in the time taken by various patients on a similar diet to develop capillary fragility.

VARIOUS DISEASES

Capillary resistance tests were carried out on twenty-three patients suffering from various diseases, which

the ulcer and haematemesis cases the response was negligible.

6. An intravenous ascorbic acid tolerance test following the intravenous administration of 1,000 mg. ascorbic acid has also been described; the maximal plasma ascorbic acid value was reached in fifteen to twenty minutes after the intravenous test dose, while the maximal urinary excretion occurred some two hours later. In normal cases 660 to 985 mg. of the ascorbic acid was excreted in twenty-four hours, of which 83 to 95 per cent. appeared in the first five hours; in patients with peptic ulceration and haematemesis 72 to 458 mg. of the ascorbic acid was excreted in twenty-four hours, although, as before, at least 80 per cent. appeared in the first five hours.

7. It has been suggested that this intravenous ascorbic acid tolerance test can be simplified for routine purposes by omitting the blood determinations and merely estimating the amount of ascorbic acid excreted in the urine in the five hours after the intravenous administration of 1,000 mg. ascorbic acid; this may not hold in cases with severe renal impairment.

8. The intradermal test for vitamin C deficiency was also carried out on these cases, and the results agreed very closely with those of the other tests, decolorization times longer than ten minutes indicating vitamin C deficiency.

9. Using the six methods for determining vitamin C nutrition, it has been shown that patients with peptic ulceration and with haematemesis suffered from severe vitamin C deficiency.

10. The severest degrees of vitamin C deficiency were found in the patients with haematemesis. It is suggested that large doses of vitamin C should be given to all subjects of peptic ulceration and haematemesis in order to saturate them as rapidly as possible.

We wish to thank the honorary medical staff of the Manchester Royal Infirmary for allowing us to use their patients; members of the nursing staff for their help in the collection of specimens; and Messrs. Roche Products Ltd. for kindly supplying us with adequate amounts of ascorbic acid in the forms of redoxon and redoxon forte.

This work has been carried out with the aid of grants from the Medical Research Council and the Dickinson Scholarship Trust Fund (B.P.).

VITAMIN C DEFICIENCY IN PEPTIC ULCERATION ESTIMATED BY THE CAPILLARY RESISTANCE TEST

BY

GEOFFREY BOURNE, D.Sc.

(From the Department of Medicine, University of Sydney)

Recent research has shown that the diet usually prescribed in gastric disease, particularly in gastric and duodenal ulcer, is deficient in vitamin C. It is probable that it is also deficient in other vitamins, notably vitamin B₁. Harris and his collaborators (1935, 1936a, 1936b), in a series of investigations on the excretion of vitamin C in seventy-four hospital patients, have found that those patients with gastric or duodenal ulcer, or dyspepsia, who had been on special gastric ulcer diets had a very low vitamin C output in the urine. Harris mentions that in guinea-pigs vitamin C deficiency sometimes predisposes to gastric ulcer, and suggests that the placing of a peptic ulcer patient on a vitamin-C-free diet may result in the production of a vicious circle. Archer and Graham (1936) have produced evidence that six out of nine patients suffering from gastric and duodenal ulcer showed a considerable degree of vitamin C unsaturation.

Troutt (1932) points out that while the diets of Sippy, Lenhartz, von Leubé, and Alvarez have been used with success for controlling the acute symptoms of peptic ulcer they make no provision for vitamin C. At first sight it might be thought that the giving of vitamin C in the form of orange juice would be prejudicial on account of its acidity, and it is found in fact that some patients have an instinctive aversion to it. However, Troutt states that about half a glass of orange juice (3 oz.) after a meal causes no discomfort in most patients with peptic ulcer. He points out that theoretically 40 litres of orange juice would be required to furnish the equivalent of the acid contained in 100 c.cm. of gastric juice of pH 1.7, and since the stomach normally secretes 3,000 c.cm. of gastric juice daily the consumption of four ounces of orange juice a day would have a negligible effect on the amount of acid present. It is of course well known that vitamin C is rapidly destroyed in the presence of strong alkalis such as sodium hydroxide, but it is very doubtful whether its stability would be significantly altered even by the considerable doses of any of the weak alkalis—for example, sodium bicarbonate, magnesium oxide, bismuth carbonate—administered to patients suffering from peptic ulcer.

The problem of the relation of vitamin C to capillary fragility is complicated by the discovery by Szent-Györgyi (Bentsáth, Rusznayák, and Szent-Györgyi, 1936) of a factor (vitamin P) occurring in close association with vitamin C which appears to have an effect on the condition of the capillary walls. For the purpose of this paper, however, no attempt will be made to differentiate between the effect of vitamin C and that of Szent-Györgyi's factor, and although the latter factor may ultimately prove to be the one responsible for the changes in capillary fragility it will be convenient to refer simply to antiscorbutic vitamins.

The present investigation was carried out with the object of ascertaining whether the deficiency of antiscorbutic vitamins in peptic ulcer described by Harris and other workers is sufficient to cause a lowering of the capillary resistance. It was also hoped that analysis of the patients' diet would shed some light on the problem as to whether

given proseptasine. The drugs, which were supplied by the makers free of charge for the purpose of this test, were prontosil album (*p*-aminophenylsulphonamide) in 5-grain tablets and proseptasine (*p*-benzylaminophenylsulphonamide) in 7½-grain tablets.

The routine was that each patient received two tablets three times a day for the first four days after delivery, and then one tablet three times a day until the end of the seventh day. The prontosil group therefore received in general a total of 165 grains of prontosil album in the course of seven days, while the proseptasine group received 247½ grains of proseptasine in the same period. One qualification must be mentioned—namely, that rather less than a half of the prontosil group received only one tablet three times a day for the whole seven days. This reduced dose was given to his patients on the request of one member of the staff, who had observed toxic symptoms elsewhere when the larger dose had been administered.

In all cases in which there was a clear probability of uterine infection a more intensified treatment was given, the soluble form of sulphonamide being injected intramuscularly in addition to the oral administration as above mentioned. Such cases included "failed forceps" outside hospital, acute pyrexia early in the puerperium, and cases of septic abortion. The drugs given intramuscularly were prontosil soluble in 2.5 per cent. solution, supplied in 10-c.cm. ampoules, and soluseptasine in 5 per cent. solution, supplied in 10-c.cm. ampoules. The routine of using drugs by injection was as follows: Prontosil soluble was given in an initial dose of 20 c.cm. followed by four doses of 10 c.cm. each at four-hourly intervals—a total of 60 c.cm. Soluseptasine was given in an initial dose of 10 c.cm. followed by three doses of 10 c.cm. each at four-hourly intervals—a total of 40 c.cm. In most potentially infected cases an injection course was begun within a few hours of delivery, and in one or two instances the first dose was actually given before delivery.

Toxic Effects

There were remarkably few cases in which any toxic effects of the drugs were observed. The most frequent and obvious toxic sign was cyanosis, which occurred in cases of the routine oral administration but proportionately more often where the oral administration was being supplemented by injections. The only other sign or symptom which we noticed at all frequently was a slight drowsiness. There were no cases of marked anaemia induced by the drugs or of *acidoses*. During the year numerous cases of diarrhoea with nausea or vomiting occurred. Although such symptoms have been reported as following sulphonamide administration it seems unlikely that any of these cases can be attributed to the use of the drugs, because a mild form of gastro-enteritis had been prevalent among the patients and staff in the hospital for two years or more. Mild albuminuria, another reported toxic sign, was not observed, and cases of toxæmia of pregnancy with occasionally massive albuminuria before delivery showed no abnormal persistence of albumin in the urine after delivery. There were no cases of skin eruption. Some cases with normal labour and spontaneous delivery manifested a persistently frequent pulse (90 to 110) during the puerperium without any other morbid signs. It was suggested that this might be the result of the drugs, but we had no clear evidence either for or against the suggestion.

Magnesium sulphate was not given by mouth at the same time as any sulphonamide preparation. If it became necessary to administer it the sulphonamide was stopped.

Ferrous sulphate was frequently administered at the same time as the sulphonamide drugs and, as might be expected, gave rise to no appreciable abnormal symptoms.

Results of Year's Working

The results of last year's working may be summarized and compared with previous years thus:

I. Local Uterine Infection; that is, Cases with One or More of the Following Symptoms—Offensive Lochia, Uterine Tenderness, Delayed Involution, and no Other Recognizable Cause of Temperature if Pyrexia was Present.

1934	1935	1936*	1937
165 cases out of 1991 (8.3%)	193 cases out of 2,016 (9.5%)	150 cases out of 2,133 (6.9%)	139 cases out of 2,241 (6.2%)

* Throughout 1936 a similar experiment was carried out with calcium sulphide. Every patient received three grains of the drug three daily from the day of delivery until she left hospital.

II. Morbid Puerperia (B.M.A. Standard) due to Uterine Infection

1934	1935	1936	1937
77 (3.5%)	74 (3.6%)	67 (3.0%)	44 (1.9%)

During 1937 forty-seven patients in all were transferred to the City Fever Hospital as being frankly infected. Of these, two died (both of pneumonia after many weeks' illness). All but five of the forty-seven had been long enough in hospital to have received a more or less complete course of sulphonamide before transfer. In only five of the transferred cases was a positive culture of haemolytic streptococci obtained after removal to the City Hospital, but these were not the five who had been transferred too early to have received the routine sulphonamide treatment. In forty-nine cases out of the 139 local uterine infections high vaginal swabs were taken and sent to Dr. C. A. Green of the Bacteriological Department of Edinburgh University. Only three of these showed haemolytic streptococci, but none conformed to Lancefield's groups A—H. Of the remaining forty-six, twelve showed a culture of *Bacillus coli*, nine of staphylococcus, one of non-haemolytic streptococcus, and one of *Bacillus proteus*.

To investigate the relative efficacy of the two particular preparations of these drugs was no part of our purpose and would have involved more clerical work than we could reasonably demand of our resident staff. Our impression was that there was no appreciable difference between them either in efficacy or in toxicity, but in order to test this point briefly we analysed the first five hundred cases of 1937, with the following results, which on the whole seem to bear out the impression just stated:

Prontosil Group (240 cases)	Proseptasine Group (260 cases)
Normal Labours— Spontaneous deliveries: No infection 93.5% Transferred to isolation ward 4.5% Uterine sepsis 1.2%	Normal Labours— Spontaneous Deliveries: No infection 92.5% Transferred to isolation ward 6.3% Uterine sepsis 1.2%
Simple Uncomplicated Forceps Deliveries: No infection 82.1% Transferred to isolation ward 17.9%	Simple Uncomplicated Forceps Deliveries: No infection 83.5% Transferred to isolation ward 5.5% Uterine sepsis 5.5%
Other Cases, including Abortion: No infection 62.1% Transferred to isolation ward 29.5% Uterine sepsis 8.6%	Other Cases, including Abortion: No infection 59.6% Transferred to isolation ward 31.5% Uterine sepsis 7.1%

included myxoedema, hyperthyroidism, diabetes, pyelonephritis and nephritis; cardiac failure, pernicious anaemia, lymphatic leukaemia, myelogenous leukaemia, cerebral tumour, pneumonia, bronchial asthma, chorea, polyarthritis, gastritis, chronic diarrhoea, and leucoplakia. Of these twenty-three patients seventeen were receiving daily doses of orange juice and the remaining six were consuming potatoes daily, with tomatoes and other vegetables and fruits, and occasional quantities of orange juice. These patients gave the following results:

6 gave no petechiae	2 gave 5 petechiae
5 " 1 petechia	1 " 7 "
3 " 2 petechiae	1 " 10 "
1 " 3 "	1 " 14 "
2 " 4 "	1 " 68 "

Total: 22 patients gave 63 petechiae. (The last patient was suffering from myelogenous leukaemia, and, since capillary fragility is well known in such cases irrespective of diet, his case was not used in computing totals or averages.) The average number of petechiae was 2.86. Statistical analysis showed that this was not significantly different from the normal average. 14 per cent. gave between four and eight petechiae, and 9 per cent. gave more than eight petechiae.

Discussion of Results

The question of the age of patients requires consideration, although Göthlin has produced evidence that even great age does not significantly affect the capillary resistance. It may, however, prove of interest to give the average age of the groups under consideration. The age averages were: gastric ulcer cases, 48.6 years; duodenal ulcer cases, 42.3 years; various diseases, 46.7 years. It was not possible to obtain the actual ages of all the normals investigated, but an estimated average is 22 to 25 years. It is apparent that the normal group is not completely comparable with the diseased group. Nevertheless the fact that the age averages of the other three groups are approximately the same provides a satisfactory check upon any possible influence of age. As regards sex, twelve out of twenty-eight gastric ulcer cases were female; only one out of fourteen duodenal ulcer patients was a female. Thirteen out of the "various diseases" group were female, and thirteen out of the twenty-two normals were female. With the exception of the duodenal ulcer cases, therefore, the distribution between the two sexes was fairly even.

It appears from the above that the lowering of the capillary resistance in cases of gastric ulcer is traceable directly to deficiency of antiscorbutic vitamins in the diet. The results were not of such a clear-cut nature in the duodenal ulcer cases, but nevertheless there appears little doubt that those cases which have been for more than ten days on the dietary regimen usually prescribed show a definite increase in capillary fragility, unless the diet has been supplemented with some potent source of antiscorbutic vitamins.

The genesis of peptic ulcer could not be correlated definitely with deficiency of antiscorbutic vitamins in the diet, but the possibility that it may play a part in some cases cannot be excluded. It seems more likely that the deficiency of antiscorbutic vitamins in the therapeutic diet may be a factor influencing the transition from the acute to the chronic condition, predisposing to delay in healing, relapses, and possibly haematemesis, but of this we have at present no definite proof.

It is of interest to note that many of these patients said that before the onset of their complaint they had no liking for fresh fruit, salads, or green vegetables, but all who expressed this dislike asserted that they were very fond of potatoes. This appears to be an interesting example of compensatory selection of diet.

Summary and Conclusions

1. Eighty-seven subjects have been examined by Göthlin's capillary fragility method. These subjects included patients with gastric and duodenal ulcer, cases of various diseases; and normal people of both sexes.

2. Hospital patients on a dietary regimen for gastric or duodenal ulcer showed a degree of capillary fragility significantly greater than normal subjects or patients suffering from other diseases.

3. Examination of the records of the patients indicates that the degree of capillary fragility is related to inadequacy of the diet in respect of antiscorbutic vitamins.

4. No evidence was obtained from the records that the development of peptic ulcer was conditioned by deficiency of antiscorbutic vitamins in the diet.

I wish to express my thanks to W. A. Carr Fraser, D.Sc., B.V.Sc., F.S.S.Lond., statistician to the Nutrition Council of the Commonwealth of Australia, for the statistical analysis of the data. I am also indebted to Professor Lambie for help and advice; and to the medical superintendents and resident medical officers of the Royal Prince Alfred Hospital, the Sydney Hospital, the Prince Henry Hospital, and the North Shore Hospital for their assistance in obtaining peptic ulcer patients.

PROPHYLACTIC USE OF SULPHONAMIDE PREPARATIONS IN OBSTETRIC PRACTICE

BY

R. W. JOHNSTONE, C.B.E., M.D., F.C.O.G.

Professor of Midwifery and Diseases of Women, Edinburgh University

At the end of 1936 my colleagues at the Royal Maternity and Simpson Memorial Hospital and I were approached by Bayer Products Ltd., the manufacturers of prontosil, and by Messrs. May and Baker, the manufacturers of proseptasine, with a request to try the effect of their products prophylactically. The amount of work to be overtaken by a limited resident staff in the hospital is so great that no investigation on strictly scientific lines and requiring much additional clerical work could be contemplated; but we agreed to make a rough-and-ready clinical experiment on a large scale by administering one or other of these drugs to every patient in the early days of her puerperium over the whole period of one year. The results of that year's work compared with those of previous years would afford reasonable ground for forming an opinion as to the efficacy or otherwise of the sulphonamide preparations in preventing the occurrence of puerperal infection.

The Routine

In order to obtain approximately equal numbers under each drug all women admitted on Monday, Wednesday, and Friday and each alternate Sunday were given prontosil after delivery; those admitted on the other days were

Clinical Memoranda

Dislocation of the Eyeball as a Complication of Oxycephaly

This case is presented because of the very unusual complication—namely, spontaneous dislocation of the eyeball.

CASE REPORT

Audrey R. was first seen at the General Infirmary at Leeds by Dr. Vining on July 12, 1935, when she was 8 months old. The mother was worried by the child's appearance and by the difficulty in breathing. Marked protrusion of the fore part of the head was noted, and the x-ray appearances were considered typical of oxycephaly. Exophthalmos was noted at that time. At 2 years of age she was seen again; she was then walking and was clean in her habits. In March, 1937, the notes read as follows: "Not so well. Very miserable. Can't get her breath. Mother thinks vision is defective. Increasing frequency of headaches."

On April 8, 1937, the mother returned from a short shopping expedition to find the child, in its perambulator, crying loudly. She brought her along to the Infirmary, and I then saw the infant for the first time. The appearances were as seen in Fig. 1. The left eyeball was completely dislocated forwards and quite immobile. The cornea was very dry, and it was impossible to see the fundus. The pupil was not dilated. An anaesthetic was given and the eye gently levered back into position with a spatula without any difficulty. In order to minimize the risk of recurrence a lateral tarsorrhaphy was performed. At the same time the right fundus was examined. Beyond slight pallor of the disk, scarcely sufficient to warrant the term optic atrophy, there was nothing of note. The next day the cornea was normal and the movements of the eye were as full as on the other side.

The child has been seen on several occasions since. There has been no deterioration of the general condition, and for the most part she appears to be quite happy. No recurrence

particular sutures involved. As a result the growing brain exerts pressure on the more yielding parts of the skull. The orbital plate of the frontal bone is depressed, and the greater wing of the sphenoid, forming the lateral wall of the orbit, is pushed forward. The capacity of the orbit is thus seriously reduced, and at the same time the axis of the orbit becomes much more obliquely directed down and out. This accounts for the divergence of the eyes so frequently noticed, and very marked in this case. The degree of exophthalmos in oxycephaly and allied deformities is proportionate to the reduction in orbital volume. In some patients it may be but slight, and in others productive of loss of the eye from lagophthalmic keratitis (Uhthoff).

What caused the dislocation in this case? The chief factors which normally keep the eye in position in the orbit are, no doubt: (a) the tension of the recti muscles. One knows how, during an enucleation, even a narrow band of undivided muscle will prevent the eyeball from coming forwards easily. (b) The degree of development and tenseness of the extensions of Tenon's capsule—that is, the check ligaments. (c) The action of the orbicularis muscle. Beyond a certain degree of proptosis, however, the plane of action of the orbicularis may be behind the equator of the globe; its action would then be reversed, and it might even exert sufficient pressure on the posterior half of the eyeball to dislocate it forward.

COMMENTARY

In an attempt to explain this case one may assume that the proptosis was so gross that the action of the orbicularis was largely nullified or reversed. In a fit of crying the spasm of the orbicularis was so great as to dislocate the globe from the orbit against the slight resistance of a very lax system of muscles and fascia. Once expelled, there would be but little tendency for spontaneous reduction of the eye into an orbit so much reduced in size.

I wish to express my thanks to Dr. Vining and to Mr. J. Foster for their kind permission to publish this case.

Leeds.

J. SHERNE, F.R.C.S., D.O.M.S.

Cardiazol in Infancy

The treatment of schizophrenia by massive doses of cardiazol has aroused considerable interest recently. A report of a case in which this drug was given in its more usual sphere might be of interest.

CASE RECORD

The patient was a male child, 11 lb. in weight when born. During the puerperium, after an unsatisfactory attempt at breast feeding, the child was given a well-known brand of condensed milk. He suffered from intermittent diarrhoea and gradually lost weight. After three weeks the diarrhoea became so marked that the parents gave him $\frac{1}{4}$ grains of hydrarg. cum creta in divided doses. When first seen by one of us twenty-four hours later he was obviously dehydrated, though at the time circulation and respiration were not seriously affected. Fortunately he was not vomiting. Brandy and slightly sweetened water were ordered. Unfortunately the baby, refusing all fluids, rapidly became worse, and twelve hours later the eyes were sunken and glazed, with the eyelids half opened, respiration shallow and gasping, the heart sounds feeble and rapid, and no pulse could be felt at the wrist. Weakness was so marked that the child could barely swallow: he seemed to have no desire for fluid, which had to be introduced by means of a pipette. He retained very little when given a rectal saline. The case looked hopeless.

FIG. 1.

After operation.

of the dislocation has appeared. The vision seemed to be no worse than before, and the mother thinks that the left eye is still the better of the two (Fig. 2).

CAUSE OF THE EXOPHTHALMOS IN OXYCEPHALY

There can be little doubt that the deformation of the orbit is the chief cause of the exophthalmos in oxycephaly and allied deformities. The basic pathology appears to be a premature synostosis of one or other group of sutures of the cranial vault, the deformity varying with the

Since September, 1936, I have been using M. & B. 125, practically equivalent to prosectasine, at the Maternity Department of the Western General Hospital. Our intention there was to put every alternate case on prophylactic sulphonamide, but this routine has not been strictly adhered to, and there has been a tendency to select cases, the more serious ones and those more likely to be followed by infection being given the prophylactic doses. Two $7\frac{1}{2}$ -grain tablets were given four times a day for the first four days and one tablet three times a day for the next three days, so that the patients who were on this treatment received $307\frac{1}{2}$ grains of sulphonamide in the week following delivery. No toxic symptoms of any significance or moment were observed, except in one case where a skin eruption occurred which was thought to be due to the sulphonamide medication.

Among 322 patients who received prophylactic sulphonamide there were twenty cases of morbid puerperia, but of these only six were due to local uterine infection, while one developed definite puerperal sepsis. Of 383 cases to which the sulphonamide was not given there were fifteen who showed signs of morbid puerperia, but of these again only six showed symptoms of local uterine infection, while one developed puerperal septicaemia. In this investigation, therefore, the general result seems negative.

My colleagues and I desire to express our thanks to Messrs. May and Baker and to Bayer Products Ltd. for their generosity in providing their drugs.

THE EARLY OCCURRENCE OF HIGH BLOOD PRESSURE IN COARCTATION OF THE AORTA

BY

E. JOAN ROOKE, M.B., B.S.,

(From the Department of Clinical Research, University College Hospital Medical School)

In recording high blood pressure as a regular feature of coarctation of the aorta Sir Thomas Lewis (1933) wrote: "We still lack records covering the periods of childhood and adolescence, during which seemingly very few cases are diagnosed. While it may be highly probable that coarctation means high pressure from a time shortly after birth to the time when cardiac failure supervenes, or death occurs from other cause, the gap that is still present in our evidence forbids us finally to draw the corresponding conclusion."

The youngest case then on record was a boy of 14 who had coarctation and a blood pressure of 150 mm. systolic (Hamilton and Abbott, 1927-8). Wilkinson (1932-3) published the case of a child of 4 years whose blood pressure was 150 mm. in the arms and who had only feeble pulsation in the iliac artery. In his case there was no evidence of anastomotic vessels. Sheldon (1932-3) published a case in the same year—that of a child of 12 in whom the blood pressure was 150 mm. in the arms and who had evidence of collateral circulation.

Case Report

The case here recorded was seen recently. The patient was a boy of 3 years. At birth artificial respiration was required, and during the first fortnight of life he became blue very easily and was treated for this with oxygen. Afterwards he was apparently normal and able to play with other children.

His parents noticed that he became blue rather easily in the cold but not at other times. On examination he was found to be a small but well-nourished child without cyanosis. His heart was enlarged, the impulse being visible 2 cm. outside the nipple line in the fifth space, and the right border of cardiac dullness 1 cm. to the right of the mid-line. Dullness to percussion was found in the first and second spaces to the left of the sternum. A systolic thrill was felt to the right of the sternum in the second space and a harsh systolic murmur maximal at this point. A systolic murmur was heard over the inner ends of all the right intercostal spaces and in the same line below the costal margin, and in the neck. A similar murmur was heard along the left border of the sternum, but it was not so extensive. These murmurs probably resulted from enlarged internal mammary arteries. The heart sounds at the apex were normal. The radial pulses were full, but neither femoral pulse could be felt, nor was there any pulsation in the posterior tibial or dorsalis pedis arteries of either leg. Anastomotic vessels were then searched for and found. There was visible pulsation from anastomotic arteries running out of the subclavian triangle and under the anterior border of the trapezius, more prominent on the right than on the left; a thrill was felt over them on the right side. A tortuous artery was seen pulsating in the right axilla, and it could be traced from under the scapula and passing deep to the pectoral muscles. Pulsation was also found on the back, in the second, fourth, and fifth right spaces, and a systolic murmur was heard over all these areas. Radiographs failed to show any erosion of the ribs. When first seen in December, 1937, the blood pressure in the right arm was 150 mm. systolic and 85 mm. diastolic measured by auscultation, and 140 mm. measured by palpation. The pressure in the left arm was always about 40 mm. lower than that in the right arm. In January, 1938, when the patient was seen again, the pressure in the right arm was 162 mm. After resting for half an hour the pressure was 160 mm., and after another fifteen minutes' rest it was 158 mm. All these readings were taken with a sphygmomanometer by palpation.

Commentary

These cases help to fill the gap referred to earlier, and indicate that the blood pressure in coarctation of the aorta is high throughout life. The demonstration of high blood pressure in the child is important because it occurs at a period of life when high pressure from other cause is extremely rare. The conclusion, which may now be formed with more certainty, that high pressure is lifelong in coarctation is of value because these cases are useful in studying the effects of long-lasting high pressure of a relatively uncomplicated kind and in comparing the arteries in upper and lower limbs where they are submitted to very different pressures.

The British X-Ray and Radium Protection Committee was formed in 1921, as the result of joint action between the Royal Society of Medicine, the Röntgen Society, the British Association for the Advancement of Radiology and Physiotherapy (now the British Institute of Radiology, incorporated with the Röntgen Society), the Institute of Physics, the London Radium Institute, and the National Physical Laboratory. The personnel of the committee was afterwards widened to include representatives from the provincial schools. Its first recommendations were issued in 1921, and these were revised in 1923, 1927, and 1934. A further revised report, dated January, 1938, has now appeared, and copies may be had from the honorary secretaries of the Protection Committee at 32, Welbeck Street, London, W.1, or the director, National Physical Laboratory, Teddington, Middlesex.

introductory and earlier chapters dealing with general matters, such as the relation between cartilage and bone, the segmental composition of the skull, the determination of the hind limit of the skull in various types of vertebrates, the craniogenic materials of the neurocranium and visceral arch skeleton, and the processes of chondrification and ossification. The systematic section of the book is a monumental record dealing with the development and general morphology of the various types of vertebrate skulls and including detailed descriptions with illustrations showing the relations to the skull of the principal arteries, veins, and nerves. This section will be of the utmost value to the beginner and the experienced morphologist alike, since the various parts of the skull in different groups of animals are compared side by side in a systematic manner, which is easily grasped, and a great aid to the drawing of general conclusions from concrete examples of skeletal structure. The book has bearings which extend far beyond the limits of the skull, and, although the palaeontological aspect of the origin of the skull has not been included within its scope, it will be of great value to palaeontologists to have before them a full and reliable record of the various structural components of the skulls of animals living at the present day. Indeed, a work specially devoted to the skulls of prehistoric and fossil animals, conceived and carried out on similar lines and gathering together the numerous separate contributions to our knowledge of the early stages in the phylogeny of vertebrate and invertebrate skulls, would be a fitting sequel to the present work. Besides dealing with the morphology of the skull the author has included a short description of the experimental work carried out by Fell, Robison, and others on phosphatase activity in relation to ossification, and the effects of the secretions of endocrine glands on cartilage formation. He has also made brief reference to such problems as the dependence of the growth of the skull on the growth of the brain, which should be of special interest to members of the medical profession. This book should be procured for every biological library and translated into all the principal languages employed by scientific workers.

The frontispiece—namely, "The Creation of Man" by Michelangelo—which has been chosen by Professors Neal and Rand for their work on *Comparative Anatomy* is a fitting introduction to a treatise which deals with the gradual evolution of man and the higher types of living animals from lower organisms. Only one-half of the original fresco in the Sistine Chapel has been reproduced, but the existence and power of the Creator, who is represented as a complete figure in the original painting, is indicated by the hand with outstretched finger to the right of the picture. The book is written with the object of providing the student of human nature with a concise account of the genetic relations which exist between the different classes and types of animal forms which have preceded the evolution of man and the higher types of vertebrates. It is a book which can be read by anyone interested in the subject—for example, clergyman, anthropologist, geneticist, geologist—without involving a prolonged study of technical details, which are apt to obscure the primary object of the reader—namely, to get a working basis of established facts on which to build his general conceptions of the origin and nature of man: the reproductive system, the influences of heredity and environment, and the interaction of different parts of the body—for example, that of the endocrine organs. The study of any one of these extensive subjects involves some know-

ledge of the others, and the present work is an endeavour to supply that knowledge in a way which can easily be assimilated by a reader who has not had a long training in practical zoology and the kindred subjects of embryology and comparative anatomy. After a brief introductory explanation of the main features of the different classes of the animal kingdom, and a fuller general account of reproduction, the authors deal with the various systems as exemplified in lower and higher types of animals. The description of the genesis and comparative anatomy of the nervous system and sense organs is specially worthy of mention, and the concluding sections on the "head problem" and ancestry of vertebrates are also valuable commentaries on the historical and recent views upon these important subjects. The book is clearly written and well illustrated.

CLINICAL DIAGNOSIS

Physical Diagnosis: The Art and Technique of History Taking and Physical Examination of the Patient in Health and Disease. By Don C. Sutton, M.S., M.D. (Pp. 495; 298 figures, 8 coloured plates. 21s. net.) London: Henry Kimpton. 1937.

In well-equipped hospitals the information provided by laboratory tests and radiological examination tends in some degree to short-circuit the more laborious and systematic methods of the old clinicians and of those practising in isolated districts. As a result medical students may not be attracted to works on physical signs and rely on the ordinary textbooks of medicine. Dr. Don Sutton, with much experience of the needs of students, has followed a more attractive course in this comprehensive volume, which not only combines the old physical signs with the new methods of radiology but is practically an atlas of clinical diagnosis. This concise text is thus admirably supplemented by successful illustrations, a good example of which is the coloured plate of bismuthia, showing the facial appearance due to prolonged ingestion of bismuth, which resembles that of the rare condition argyria. The radiographs are well reproduced, and there are useful pairs showing the naked-eye and radiological appearances of the same condition. Stress is rightly laid on the importance of taking an accurate clinical history. Without overdoing it, the portraits of medical pioneers and photographs of the title-pages of their works give an interesting historical touch.

ORTHOPAEDIC PRACTICE

A Practice of Orthopaedic Surgery. By T. P. McMurray, M.B., F.R.C.S.Ed. (Pp. 471; 178 figures. 21s. net.) London: Edward Arnold and Co. 1937.

Before David went out to do battle with Goliath Saul arrayed him in his own heavy armour. But his own youthful agility, his sling, and the five smooth stones were of more use to him than the cumbersome equipment of the older man. To-day the Davids in our medical schools are being burdened more and more with weighty instruction in this and that special branch of medicine, until now even the benevolent Sauls that would send them forth are beginning to realize that something must be done to make the equipment lighter and allow for greater mobility. The teachers in the special departments, particularly, are required to confine their teaching to essentials, and this applies to the written as much as to the spoken word. Orthopaedics is a comparatively young subject, but most students are appalled by the size of the textbooks dealing with this important branch of surgery. No book has hitherto been produced which the average student has time to read or the capacity to digest. For this reason

Two drops of cardiazol were introduced into the first feed by pipette of weak condensed milk, and as this seemed to give the child some desire for further fluid it was repeated four-hourly. After the first dose of cardiazol four minims of pituitrin were injected hypodermically and repeated once six hours later. As a result of this treatment the circulation improved, but the most interesting feature was the increase in appetite after every dose of cardiazol. After forty-eight hours the baby seemed out of danger, so cardiazol was discontinued. The next day he was not so well; his circulation was sluggish and he was again apathetic to his feeds. The administration of cardiazol was resumed and he took his feeds more readily. His general condition also improved. After several days the cardiazol given was gradually reduced, and after a week the baby made an uneventful recovery. The condensed milk feeds were replaced by ostermilk (full-cream), which he took readily. He is now 7 months old and weighs 22 lb.

We would be interested to hear of any similar case occurring in England. Excellent results in the treatment of malnutrition with collapse in infants have been reported in German literature by Koschate (1935) and Hoffmann (1937).

Pneumococcal Meningitis treated with Prontosil

The following interesting case, in which pneumococcal meningitis was treated with prontosil, seems worthy of record.

CASE RECORD

A man aged 26 was admitted to hospital on December 27, 1937, complaining of photophobia, with some stiffness and pain in the head and neck. On examination definite neck rigidity and slight head retraction were found, and Kernig's sign was strongly positive. The temperature was 100° F. and the pulse rate 98. He gave no history of any recent lung, ear, nose, or throat affection, although he had had influenza about a month previously and had never felt well since. A lumbar puncture was performed on admission. The pressure was increased and the cerebrospinal fluid was opalescent. The pathological report on the cerebrospinal fluid was: total cells, 5,500; polymorphs, 98 per cent.; some Gram-positive cocci were seen on direct smear—in all probability pneumococci.

The patient was treated with large doses of prontosil, and three days later a second lumbar puncture was performed. The pressure was normal and the organism was again seen, proving on culture to be Type I pneumococcus. Administration of prontosil was continued. The patient's temperature remained raised for about five days; Kernig's sign gradually diminished, as did the headache and stiffness of the neck. On January 8, when a third lumbar puncture was performed, the cerebrospinal fluid was normal and the culture sterile.

This, as far as I know, is the second reported case of pneumococcal meningitis treated with prontosil. In the first one (*British Medical Journal*, 1937, 2, 1204) it was doubtful if the successful issue was due to repeated lumbar puncture or to prontosil. In the present case, however, it is obvious that whatever the cause of the recovery it was not due to repeated lumbar punctures.

My thanks are due to Dr. A. M. Barron, senior physician to this hospital, for permission to publish this case.

Cornelia and East Dorset Hospital. House-Physician.

Reviews

PAEDIATRIC THERAPEUTICS

The Infant: A Handbook of Modern Treatment. By Eric Pritchard, M.A., M.D., F.R.C.P. (Pp. 744; coloured frontispiece; 47 figures, including 4 plates. 18s. net.) London: Edward Arnold and Co. 1938.

Written essentially for the general practitioner and based in part upon verbatim reports of postgraduate lectures extending over many years Dr. Eric Pritchard's handbook will be widely welcomed for its practical outlook. As its title suggests, treatment is the book's primary concern, pathology and aetiology only being mentioned in order to justify some form of treatment, diagnosis in order to enable the practitioner to be sure "that he is looking at the right paragraph," while prognosis is not considered. If this method of approach is accepted then the volume must be acclaimed successful. Early chapters deal with infant feeding, in which the author has always been particularly interested. His methods of using cow's milk will not be generally accepted, nor is it of value to mention the old "Grade A" milk now no longer recognized by the latest Order of 1936. In other sections there will also be found methods and views which are open to criticism. For example, few paediatricians would agree that "congenital pyloric stenosis" is entirely caused by spasm, likely to be successfully relaxed by drug treatment "in the great majority of cases." On the other hand, some original methods suggested will be certain of a wide acceptance. For example, the use of thyroid extract for premature babies and of tannic acid for sore buttocks appear to be well worthy of a trial.

It is impossible to do more than select a few examples for criticism or praise, for there are over seven hundred pages in this book, and few of them can be read without benefit by the specialist or the general practitioner. We hope that this permanent record of a lifetime devoted to the care of sick infants will be widely read.

MORPHOLOGY AND COMPARATIVE ANATOMY

The Development of the Vertebrate Skull. By G. R. de Beer, M.A., D.Sc., F.L.S., F.Z.S. (Pp. 515; 143 plates. 30s. net.) Oxford: Clarendon Press; London: Humphrey Milford, Oxford University Press. 1937.
Comparative Anatomy. By Herbert V. Neal and Herbert W. Rand. (Pp. 739; 540 figures. 21s. net.) London: H. K. Lewis and Co., Ltd. 1936.

The Development of the Vertebrate Skull, by G. R. de Beer, is a great work, dedicated to the memory of four pioneer workers on the morphology of the skull—namely, Thomas Huxley, Kitchen Parker, Ernst Gaupp, and van Wijhe. It will be of world-wide interest to morphologists, human anatomists, and embryologists, since it embraces the developmental history and comparative anatomy of the skull throughout the whole range of the vertebrate kingdom. It deals in a systematic and uniform manner with the structure and phylogeny of the vertebrate skull and contains a mass of information, presented in a uniform manner with respect to nomenclature and classification, which will prove to be of immense value to workers in this field for many years to come. This is a consideration which the author has anticipated and provided for by suggesting certain special and general problems which require investigation. Of special value to workers who are embarking on some particular piece of research will be the

geographically, and reference is thus facilitated. It is mentioned that many changes take place each year, and every effort has been made to ensure accuracy. Telephone numbers are given, and there is also a statement of the services which each institution is prepared to render; in some cases nurses are available for outside work.

Preparations and Appliances

RAPID RADIOGRAPHY FOR THE SMITH-PETERSEN OPERATION

Mr. ROBERT G. W. OLLERENSHAW (Manchester) writes:

It is probably safe to say that at the present time 95 per cent. of fractures of the neck of the femur are being treated by one or other modification of the Smith-Petersen nailing operation. This entails scrupulously careful checking of the position of the guide-wire. It is essential to take at least two films, and it may be necessary to take several more before the ideal position of the guide-wire is achieved. In most hospitals the films, taken by a portable outfit in the theatre, are carried some distance for processing, and in many cases, even when one of the modern high-speed developers is used,

make the atmosphere of the theatre unpleasant, and other modifications were involved to suit the x-ray emulsion. At normal theatre temperature development and fixation are complete in one minute. The film only requires washing to be reasonably permanent, but in practice this point is unimportant, since it is rarely necessary to preserve these intermediate films. Having reduced the process to this degree of simplicity, the production of a portable dark-room is easy. Our pattern consists of a box, 18 inches by 18 inches by 24 inches, fitted with light-tight drop-on lid, and with two 8-inch armholes in the front. To these holes are fitted sleeves of green felt (an opaque type is essential) 16 inches long, with elastic round the cuff. The sleeves are clamped to the box by plywood rings, ensuring a light-tight joint. Internally, the box has a 10-inch shelf extending from the back and resting loose on battens half-way up the sides of the box. Running fore and aft across the middle of the floor is a strip

FIG. 2.—Front elevation and section through AA.

FIG. 1.—Portable dark-room.

an interval of at least fifteen minutes may elapse before the wet films are returned to the operating theatre. If this period of waiting has to be repeated two or three times it involves a long and tiresome delay both for the staff and for the patient. By using the method here described it has been found possible to produce an entirely adequate film in one minute. An ordinary portable developing box is a great time-saver, but if it is to contain three dishes each large enough for a film twelve inches by ten inches, for developer, water, and fixative, it is bound to be unwieldy, and, moreover, it is only too easy to get the film into the wrong dish when working by touch alone. It occurred to us that, since the only requirements are a bony outline and the shadow of the wire, no fine detail being needed, some modification of the old "while-you-wait" process would solve all the problems, since it involves only one dish and can be made to work extremely fast. On these lines, therefore, we have evolved the developer formula given below. The ammonia of the old method had to be eliminated, since it was strong enough to

of wood 1/8 inch thick, across which the dish is balanced, and which then acts as a rocker-bar. Any competent joiner can build the outfit for twenty to thirty shillings. It should be blacked internally, and fitted with handles as shown in Fig. 1.

In use the cassette is placed on the shelf, open side to the front, and the lid closed. The operator's hands are placed in the sleeves, and these are invaginated into the box. He opens the cassette, slides the film round the edge of the shelf into the dish, and rocks it with a finger at each end. The rocker-bar not only makes this easy but, by limiting the excursion of the dish, makes the outfit almost non-spillable. After removal of the finished film the loose shelf allows the dish to be removed and emptied. Owing to the fact that fixation is proceeding at the same time as development, and is therefore tending to reduce density, we find it best to double the normal exposure time for the tube in use. The developer does not keep too well when mixed, and for that reason we keep it as three components, given below. Mixing for use only takes a few seconds. Our experiments have been made with the Ilford improved fast film, double-coated.

Formulae

A. Sodium sulphite (anhydrous)	100 grammes
(or crystalline, 200 grammes)	
Sodium carbonate (anhydrous)	60 grammes
(or crystalline, 160 grammes)	
Sodium hydroxide (stick)	50 grammes
Water to	1,000 ml.
B. Sodium thiosulphate (crystalline)	375 grammes
Water to	1,000 ml.
C. Hydroquinone	30 grammes
(Conveniently kept weighed out and wrapped as powders. Store in an airtight tin.)	

For use, dissolve the hydroquinone in 200 ml. of hot water, and add 400 ml. each of A and B; mix well. This keeps for about two days when mixed. Any fine precipitate of sulphur may be disregarded.

While the fundamental ideas are nearly as old as photography itself, we feel that this application of them to modern needs should be of some value. A Smith-Petersen pin was introduced satisfactorily at Salford Royal Hospital about two weeks ago, using the technique described above and with the Hey Groves direction finder, in twenty-three minutes.

the completion of Mr. McMurray's work has been awaited with more than usual interest, because of his eminence as a teacher of orthopaedic surgery. He has covered the ground in 460 pages, which means that the volume is within the scope of the senior student. Noticeable attention is given to principles, though perhaps less than one would have expected from a spiritual descendant of Hugh Owen Thomas. We had hoped to find a departure from the traditional approach (tuberculosis of joints, infantile paralysis, congenital deformities, etc.), and greater emphasis on restoration of function rather than on specific diseases. Such a book might suffer from being too long, for the author must still describe the diseases and deformities that impair function; yet descriptions of operations, not detailed enough for the orthopaedic surgeon and of little use to the student, could be omitted. For example, in the chapter on infantile paralysis no clear distinction is drawn between operations for correcting deformities the result of faulty treatment and the reconstructive procedures for the relief of inevitable deformity (which generally means residual paralysis) due to the severity of the original disease. The first can be avoided by good treatment, but not the second. We are told that "no definite rules as to procedure can be given, and each case must be dealt with according to the condition found." But surely there must be at least a few guiding principles in planning an attack on a paralysed limb—such, for example, as dealing with the hand before considering stabilization of the shoulder in a case where the upper extremity is seriously involved; and avoiding elongation of the Achilles tendon where a moderate equinus position of the foot is helping to stabilize a knee lacking an active quadriceps.

It is good to find that Mr. McMurray is an unashamed conservative, and he has defined the grounds for his conservatism in words that deserve repetition:

"Orthopaedic surgery, which possibly may best be described as the surgery of the framework of the body, has developed from the surgery of the deformities of children and the so-called bone-setting of the unqualified practitioner. This branch of medicine is concerned chiefly with errors in the motor system—the result of disease or injury—and in his outlook the orthopaedic surgeon must consider the future rather than the immediate condition of the affected tissues. . . . As orthopaedic surgery is concerned largely with growing and developing tissues the outlook of the surgeon should be essentially conservative. Operations such as moulding and manipulation are usually preferable to the more radical measures which are naturally more attractive, especially to the younger surgeon, and this tendency to conservatism should not be discarded even though the simple procedures are sometimes followed by a recurrence of deformity. Extensive bone operations, which must interfere with growth, should be avoided as far as possible, and if such measures are necessary they should always be postponed until this danger has disappeared."

Mr. McMurray has other reasons for conservatism. Many elaborate operations on bones and joints are sound in conception and pretty to watch. They have one drawback—they give the desired result in only a minority of cases. These operations are sometimes accorded a place of honour in textbooks, but the impression given of their merits is too often misleading. This sentence is typical of the author's attitude: "The results of this procedure are very rarely satisfactory, and do not as a rule justify the surgeon's enthusiasm." One can rarely quarrel with his judgment. No informed surgeon will agree with all of Mr. McMurray's views, for he is dealing with a young branch of surgery in which controversy is still lively; but no one will deny that his teaching is funda-

mentally sane and safe. This book can be recommended with unreserved enthusiasm to the student, both before and after qualification; and it may be read with profit by practising surgeons who are humble enough to admit that they sometimes lose the guiding light of principle in the fog of the daily detail of clinical practice.

PSEUDOCYCLISIS

Pseudocyclosis. By George Davis Bivin, Ph.D., and M. Pauline Klinger, M.A. (Pp. 265; 18 tables; 5 plates. 17s. 6d. net.) Bloomington, Indiana: The Principia Press, Inc.; London: Williams and Norgate, Ltd. 1937.

Some years ago Dr. George D. Bivin of Illinois began a systematic collection of all the published works on pseudocyclosis, with a view to applying the knowledge so gained to the elucidation of certain psychological disorders. He was unable to finish the work, but it has since been completed by M. Pauline Klinger, and the result of their combined efforts is embodied in the first monograph on the subject. It records statistically all the 444 case-histories published to date, and classifies *in extenso* their relevant details under a variety of headings. The result is an exhaustive account of the aetiology, diagnosis, and treatment of a most difficult disorder, for though comparatively rare pseudocyclosis always presents a problem at once distressing and disconcerting. For this reason alone any addition to our knowledge concerning it is of real value, and though the present work emphasizes the extreme variety of the symptomatology it also demonstrates the importance of very careful examination if the deplorable mistakes which have apparently so often been made in the past are to be avoided. The book is well indexed and contains a complete bibliography, and is in general a most valuable addition to the literature of an important and obscure subject.

Notes on Books

The thirty-ninth edition of *First Aid to the Injured*, the authorized textbook of the St. John Ambulance Association (price 2s.), differs from its predecessors in the special attention given to burns and the method of transporting a patient with spinal injury. It is considered that the treatment of extensive burns and scalds by tannic acid is a matter of skilled technique and outside the scope of first aid; the application of a warm solution of baking soda is advised. With regard to the treatment of spinal injuries, although no uniformity among the various authorities was found on inquiry, it has been decided to modify the methods to be observed by first-aiders in transporting these cases. Chapters on shock and its treatment and on the routine examination of a patient have been added, and there are many new illustrations. It is mentioned that the membership of the Brigade at home and abroad now exceeds 100,000. The Brigade also provides fully trained persons for the Royal Naval Auxiliary Sick Berth Reserve, the Military Hospitals Reserve, and Voluntary Aid Detachments.

We have received a *Short History of the Croatian Medical Society* (Zagreb, no price given), of which the Croatian text is followed by German, French, and English translations. The society was founded in 1874 by Dr. Franjo Milicic, the district medical officer of Zagreb, and soon gained a high reputation, holding regular meetings at which scientific and social questions were discussed.

Nursing Homes (1938) is now in its eighth year of publication as a directory of registered nursing, convalescent, and mental homes in England, Wales, and Scotland (Benn Brothers Ltd., 3s. 6d.). The information is arranged

BRITISH MEDICAL JOURNAL

SATURDAY MARCH 12 1938

THE FUNCTION OF VITAMIN C

The availability of vitamin C in the pure form as ascorbic acid has stimulated many workers to try to determine its function in the human organism. Almost the first problem that was tackled was the question of how much vitamin C was needed by man. At first the appearance of ascorbic acid in the urine was taken as an indication that the tissues of the body were saturated, but later it was shown that some ascorbic acid was excreted before this happened. The saturation of the tissues could be judged only by a determination of the total intake and output of ascorbic acid. Portnoy and Wilkinson have reported in a recent issue of this *Journal* (February 12, 1938) the results of their application to human patients of Rotter's skin test for the content of vitamin C. It is based on the time taken to decolorize 2:6-dichlorophenolindophenol when injected intradermally. From a comparison of their figures with the corresponding figures obtained by Abbasy's saturation test and those for the vitamin C content of the blood they conclude that if five minutes or less are required to decolorize the specified amount of dye saturation of the tissues with vitamin C may be assumed, but if the time required is longer than ten minutes a deficiency must be assumed. They consider the method of value as a rapid clinical test for vitamin C deficiency. The values corresponded roughly with what might have been expected from the diets of the different patients (that is, as containing much vitamin C, a moderate amount, or almost none). They do not draw any conclusion as to the amount of ascorbic acid required by man per day. Wackholder and Hamel,¹ however, have come to the conclusion that a daily dose of 250 mg. must be given in order to get an appreciable increase in the tissues; they postulate a specific dynamic action for ascorbic acid, as for proteins. Göthlin and his co-workers,^{2,3} after modifying certain details of the capillary resistance test and investigating the limits of its usefulness, came to the conclusion that the absolutely indispensable daily requirement of a healthy adult is from 0.39 to 0.48 mg. per kilogramme of body weight. It is obviously desirable to allow more than this in planning a dietary, and

it is obviously imperative that the amount given in curative treatment should be much greater. Giroud and his colleagues⁴ determined the ascorbic acid content of the suprarenals, liver, and kidneys immediately after the (violent) death of twenty-six normal persons. They found the content of the kidneys less than that of the liver, and that of the liver less than that of the suprarenals. The content of organs of the older people was less than that of corresponding organs of the middle-aged, and those of the latter were less than those of the children. All the determinations were lower than were found in the same organs of well-fed guinea-pigs: they concluded, therefore, that man in general does not have enough vitamin C and that his diet must be regarded as inadequate in this respect.

As for the functions of vitamin C in the animal body, it has been shown⁵ that formol toxoid becomes weakened in its antigenic property and that the virulence of tetanus toxin is slightly weakened through contact with moderate doses of ascorbic acid, although, strangely enough, higher and lower concentrations of ascorbic acid were without effect on either the toxoid or the tetanus toxin. According to Kligler and others⁶ ascorbic acid inactivates diphtheria toxin under both aerobic and anaerobic conditions at a rate depending on the concentration of the vitamin and the temperature of incubation, though the action on preformed toxin is slower than it is on the toxin during production. The action may be one of oxidation and reduction, but glutathione did not produce the same effect. The suprarenals of guinea-pigs treated with diphtheria toxin showed a loss in vitamin C content. These workers suggest that the modified non-toxic type of infection so common in Palestine and other subtropical and tropical regions is ascribable to a higher vitamin C reserve or intake of the inhabitants of these regions, and they are at present making an investigation of this point. They also call attention to the post-diphtheritic appearance of scurvy in some children. The value of the "sekale preparation" in preventing post-partum bleeding has been exceeded by the value of ascorbic acid.⁷ In surgical infections, both acute and chronic, increased intake of vitamin C has proved beneficial, and Lauber, Bersin, and Nafziger⁸ have shown that in animals whose vitamin C metabolism was controlled there was unexceptionally an increased need for this vitamin after experimentally induced streptococcal infections. The same observers⁹ have demonstrated that, in rabbits, during the narcosis produced by

JOINT TUBERCULOSIS COUNCIL

The meeting of the Joint Tuberculosis Council on February 19 was specially noteworthy since it marked the end of Dr. Ernest Ward's long period of secretaryship. Not only was Dr. Ward the originator of the council, but he has served as its secretary during the fourteen years of its existence. The chairman of the council (Dr. S. Vere Pearson) and Dr. G. Lissant Cox, the previous chairman, paid special tribute to the excellent service Dr. Ward has given. He is succeeded by Dr. J. B. McDougall (Preston Hall, near Maidstone, Kent).

The council decided to proceed with the publication of the exhaustive report on sputum examination prepared by the committee of which Dr. W. H. Tytler (Cardiff) is the convener. This report covers the whole field of sputum examination in an exemplary manner, and is likely to be in much demand. The secretary reported that the Ministry of Health had replied to a communication regarding the classification of patients who showed tubercle bacilli in discharges from glands, bones, and joints. The reply was to the effect that "Tb. plus" or "Tb. minus" relates only to patients suffering from pulmonary tuberculosis, and that patients showing tubercle bacilli in discharges from bones, joints, glands, etc., are not to be classified as "Tb. plus." There has apparently in the past been much ambiguity on this point, and the council expressed the view that the Ministry of Health should give publicity to this important decision.

Dr. Ernest Ward (Devon) presented his biennial report. This is valuable in so far as it gives a collective summary of the work accomplished by the council during the past two years, and there is an imposing account of the work of various committees. Special consideration is given in Dr. Ward's report to the microscopical examination of sputum, the culture of tubercle bacilli, examination of contacts, the results of artificial pneumothorax treatment, tuberculosis amongst nurses, milk, tuberculin, and sedimentation.

Memorandum on Nursing Services

The council gave lengthy consideration to the evidence to be submitted to the Interdepartmental Committee on Nursing Services. The memorandum on this subject was presented by Dr. G. Lissant Cox (chairman of the committee) and Dr. Esther Carling (secretary). The memorandum is a full and comprehensive account of the nursing problem in relation to tuberculosis institutions in this country; though certain difficulties had to be overcome by the committee a large measure of agreement was reached, and the evidence as a whole was accepted by the council. Matters concerning the inauguration of a supplementary register, the hours of duty of nurses, the definition of "assistant nurses," and the factors influencing the recruitment of nurses for tuberculosis institutions are all discussed in detail. Special consideration is also given to the training of nurses and to the employment of tuberculous ex-patients as nurses—a matter previously dealt with by the council in its Employment Committee's reports. Important suggestions for improved remuneration and conditions of service for nurses in sanatoria and hospitals for tuberculosis are given, and in the appendices to the memorandum there are examples of the treatment and nursing work done in modern sanatoria, time-tables for staff nurses and night nurses, and minimum scales of salaries proposed.

Dr. G. Jessel, the convener of the Radiological Interpretation Committee, was able to report that he had been successful in co-opting on his committee representatives of the radiological societies in this country, and that a comprehensive report would be available in due course. The work of the Joint Tuberculosis Council in organizing postgraduate courses for tuberculosis officers and others is now well known, largely through the efforts of Dr. W. Brand (Camberwell). Suggestions for further courses at home and abroad are under consideration.

L.C.C. CONSULTANT AND SPECIALIST SERVICES

It is proposed by the London County Council to continue for a further year, with certain modifications, the existing consultant and specialist services. The number of routine sessions to be worked by consultants and specialists at grouped general hospitals and other establishments has been limited to a total not exceeding 205 a week.

Anaesthetists' Sessions

The proposals now made will add about another fifty sessions. The greater number of these will be regular anaesthetists' sessions. The use made of the services of consultant anaesthetists varies considerably at different hospitals. It is considered that it would be a decided advantage for the medical staff at hospitals to be augmented by the regular services of consultant anaesthetists, and it is proposed that such consultants should be allocated to general hospitals for a fixed number of sessions a week, each approximately of two and a half hours' duration. Anaesthetists employed for regular weekly sessions will be paid at the usual scale for consultants and specialists—namely, £125 a year for one session a week and £75 a year for each additional weekly session, with additional payment of two and a half guineas a visit for each emergency attendance in addition.

Orthopaedics : Radiology : Obstetrics

Six additional sessions are required in connexion with orthopaedic surgery in order that each of the general hospitals which treat fracture cases may be visited weekly by a consulting orthopaedist. Certain rearrangements are to be made with regard to the service of full-time radiologists, and in addition to the two full-time radiologists at present employed a third is to be appointed for duty at five hospitals. This will mean that eleven sessions hitherto given by part-time consulting radiologists will no longer be required.

The arrangement whereby the consultant services in obstetrics and gynaecology at Fulham and St. Mary Abbots Hospitals have been undertaken during the last three years by the professor of midwifery at the British Postgraduate Medical School is considered no longer necessary, and the work is to be done by an officer of the Council—that is, a part-time obstetrician and gynaecologist. Four such officers are already employed in the hospitals service, and the arrangement whereby they have assumed responsibility for the obstetric and gynaecological work has proved very satisfactory. The rate of remuneration attaching to the new position will be £800 a year.

Neuro-surgery and other Specialties

The services of neuro-surgeons are being increasingly required, and it is proposed to create a panel similar to the existing panel of consulting neurologists. In practice the fees for neuro-surgeons when required in special cases have been fixed at two and a half guineas a visit for consultation and five guineas a visit when an operation is performed, irrespective of the number of patients seen or operations performed. Having regard to the highly specialized nature of the work, these rates of remuneration are considered reasonable for the new positions.

Other arrangements are that the number of sessions to be worked by thoracic surgeons at tuberculosis hospitals and at general hospitals (other than St. Mary Abbots, where special provision is made) is to be fixed at not exceeding 230 a year and 170 a year respectively, that the number of sessions to be worked by ear, nose, and throat surgeons at the medical tuberculosis hospitals shall be fixed at not exceeding 140 a year, and that one of the consultants for cardiovascular disease at Lambeth Hospital shall be employed for three sessions a week at a salary of £275 a year, which is the standard rate for "group" scheme consultants.

preparation of food. In addition to the photographs a large model has been constructed, measuring some 230 square feet, of an ideal sports centre for a provincial town of some quarter of a million inhabitants. It is intended to show local authorities the kind of thing that can be done, with Government assistance, under the Physical Training Act. One of the first schemes to be put in hand under that Act is at Stockton-on-Tees, and of this a sketch design is shown. It is a space 28 acres in extent, with a stadium, gymnasium, swimming-bath, tennis courts, and provision for other games, as well as a children's playground.

On public baths and stadiums the old Romans exercised their skill, but if this exhibition is a fair index to what is taking place, especially on the Continent, the modern architect is well in line with those of his calling who flourished in the time of Titus and Diocletian. One instance in this country is the Stoke Park swimming-bath at Guildford, but a large number of photographs are shown of swimming-baths in Germany, Italy, and Switzerland which are on a very ambitious scale. A model has also been sent from Berlin of the Olympic stadium and physical training centre there. In the section dealing with housing and factories the value of good natural lighting is emphasized, as can well be done by means of photographs. It is also encouraging to notice from how many parts of industrial England come illustrations of excellent provision for pithead baths at collieries, washing facilities in factories, also works canteens and other arrangements for the comfort and health of the worker.

The architect claims to play his part in preventive medicine, and shows in evidence modern works for refuse disposal, water supply, and food distribution. In many of these respects, and especially in the arrangements of classrooms in schools, the cleansing of streets, and farmyard hygiene, the present generation can give itself a pat on the back; but there are plenty of photographs of things as they are to-day to recall it to humbleness, especially the pall of smoke over towns. The exhibition is full of human interest; those who have looked upon utilitarian architecture as a flavourless subject, lacking in emotional quality, will be pleasantly disillusioned.

HOST SUSCEPTIBILITY TO COLDS

In an amusing letter some time ago Dr. L. W. Batten¹ tilted at the present enthusiasm for nutrition, and pointed out that the well-fed population of Hampstead were heirs to all the common ills of the flesh. "What matters is that we leave behind the strain and stress of responsible work, the town, its clothes and its crowds,

we live simply out of doors and we exert our muscles. The minor ailments and the malaise, which have withstood excellent dieting for months, vanish in a week." Experiments by Spiesman and Arnold² on susceptibility to the common cold support the view that activity of the skin and exercise in the open air are at least as important as good diet in the avoidance of infection. They classify colds into infectious and allergic groups. Even when protein hypersensitivity cannot be demonstrated by skin reactions the two varieties of cold can usually be differentiated by the history and by the character of the nasal secretions, which become mucopurulent with infection but remain serous and eosinophilic with the allergic reaction. Infectious colds can be subdivided into true influenza and epidemic catarrh or the common cold. Influenza is a frank infection but there is a good deal of evidence that the seasonal incidence of the common cold is not explained by overcrowding in bad weather and increased opportunities for infection, but that it is due to disturbances in the heat-regulating function of man as a result of climatic changes. Leonard Hill observed that the nasal mucosa was affected by changes in the temperature and humidity of the environment. The mucosa of the nose becomes flushed and swells when the subject is placed in a moist warm atmosphere; when he passes to a cold atmosphere the mucosa quickly becomes pale from constriction of the blood vessels but still remains thickened and swollen. Spiesman and Arnold found that the individual suffering from repeated infectious colds has an altered vasomotor reaction of the upper respiratory mucosa to thermal stimuli applied to the skin. In the normal individual the temperature of the nasal mucosa falls abruptly with the application of a cold stimulus to the skin, and then gradually recovers and returns to approximately normal within ten minutes, even though the stimulus is still applied. In the individual with frequent colds vasoconstriction in the nasal mucosa is much more gradual and persists for from several minutes to two hours. In the hypersensitive or allergic subject the reaction of the nasal mucosa is the opposite of normal—an increased temperature when a cold stimulus is applied to the skin and a decreased temperature when heat is applied. The best preventive measure in colds of both groups, the infectious and the allergic, was found to be vasomotor massage, which was applied to the subjects in their own homes, each receiving instructions to take a hot bath and a cool or cold shower when rising each morning and to repeat this if possible each evening before dinner. At first all products made from wheat—that is, white-flour breads, pastries, pies, etc.—were eliminated from the diet, and afterwards over-indulgence in carbohydrates was still guarded against. Physical exercise was looked upon as an important adjunct of the daily regime, and the mental state was also important, as any worry or mental strain tended to offset the advantages derived from hydrotherapy and diet. With such treatment the vasomotor response returns to the normal pattern, there is an absence of head colds, and the subjects enjoy a better state of well-being and continue the hygienic treatment for this reason.

local anaesthetics, by chloroform, ethyl chloride, etc., there is an increased output of ascorbic acid in the urine. Intravenous injections of "redoxon" (Merck's ascorbic acid) compensated for the loss. Lauber and his colleagues¹⁰ have also demonstrated that there is no increase in the output of ascorbic acid in the urine after simple fractures of the fore-leg of the rabbit, but that there is after a compound fracture. Moreover, callus formation is not accelerated by giving ascorbic acid in doses greater than are needed to correct the hypovitaminosis. Another result, recorded by Fischer and Oehme,¹¹ which may prove important is that the administration of large doses of vitamin C reduced the output of creatine in the urine of rats suffering from thyroxine creatinuria.

Work previously published on the influence of vitamin C in controlling the development of poliomyelitis in monkeys which had been experimentally infected has been confirmed, with better results apparently from a product extracted from natural sources than from a synthetic product. The former contained 2.5 per cent. of unidentified impurities absent in the synthetic product. The concentrations of ascorbic acid in the tissues of normal monkeys (rhesus) were found to be comparable to those in the tissues of other animals that cannot synthesize vitamin C. They can be increased by prolonged parenteral administration of ascorbic acid. In monkeys suffering from poliomyelitis these figures are slightly below the normal average during the height of paralysis or in early convalescence. When inoculated monkeys were found to have resisted the disease distinctly hypernormal levels of vitamin C were found in the central nervous system. Why certain individuals can attain this level of storage of the vitamins and others cannot remains unexplained.¹² A simple method of determining the vitamin C content of the blood has been devised,¹³ and by its use it has been demonstrated that there is always a higher ascorbic acid content of the foetal than of the maternal blood. It was often twice as high and once was found to be four times as high. This week Drs. Portnoy and Wilkinson give an account at page 554 of an investigation into the vitamin C content of the blood and of urine of normal persons, patients with peptic ulceration, and patients with haematemesis. The six different methods of examination used all gave comparable results. All the patients with peptic ulceration or with haematemesis were observed to be suffering from severe vitamin C deficiency, and vitamin C therapy was strongly recommended. Mr. Geoffrey Bourne of

the University of Sydney, using the capillary resistance test (as recommended by Göthlin), at page 560 confirms Portnoy and Wilkinson's findings in hospital patients with gastric or duodenal ulcer and on a dietary regimen deemed suitable for this condition. There was, however, no evidence from the records that such a deficiency in the diet was responsible for the development of peptic ulcer.

After all the discussion of methods of determining whether a person's intake of ascorbic acid is adequate or not, it is a relief to know that the ascorbic acid content of fruits and vegetables (or at least of most of them) can be determined with a fair degree of accuracy.¹⁴ The increase in the amount of vitamin C can be followed as the fruit ripens, and comparisons between different varieties, at the same times and in similar degrees of ripeness, can be made. The whole trend of research on vitamin C in recent years well illustrates Galileo's precept: "To measure all things that can be measured and to make measurable all things which cannot yet be measured."

BUILDINGS FOR HEALTH

The genius of the architect has for ages been evident in buildings for worship and for government, and more recently for commerce and industry, but it still seems strange, though it should not, for the word architecture to be used in association with buildings or lay-outs intended for sport, physical training, and the health concerns of a community. The Royal Institute of British Architects has arranged an exhibition, which is open at its premises in Portland Place, London, W., until the end of the month, to illustrate, chiefly by photographs, how the architect's intervention causes the best use to be made of the available space and material, and results in buildings which not only serve their purpose but satisfy the eye. It is no small gain if, at a time when recreative physical training is being so strongly urged, the places intended for sport and recreation, the baths, stadiums, rinks, and so forth, are given a certain grace and dignity. They should not be pompous, the prevailing note should be simplicity and gaiety, and it needs the trained architect to impart it. The exhibition is in four sections. One of them illustrates town planning, with suggestions for the best arrangement of open spaces and park ways; another is concerned with healthy living and working conditions in houses, factories, and streets; a third, with the public services, sanitation, and so forth; and a fourth, with the processing, distribution, and

precautionary measures of isolation were taken, showed, when slaughtered, tuberculous lesions in a much greater proportion than did the controls, suggesting that the vaccination might have had a predisposing rather than an immunizing action. Under the same conditions animals vaccinated with living B.C.G. contracted infection to the same degree as the controls. On the other hand, when precautions were taken to isolate the vaccinated calves for a certain period, during which they were fed on milk free from tubercle bacilli, B.C.G. conferred considerable resisting power, both against natural contagion and against artificial infection. In one experiment where the infecting dose was large enough to kill all the unvaccinated calves and those treated with killed bacilli, out of the five calves vaccinated with B.C.G. four were "unharmful" and one showed small nodules in a mesenteric gland. In another experiment none of the four calves vaccinated with B.C.G. or with live human bacilli contracted the infection, although the infection was enough to cause the development of tuberculous lesions in three out of four animals in each of the other groups—that is, those not vaccinated or vaccinated with dead bacilli.

TREATMENT OF VARICOSE VEINS

For many years it was customary to treat varicose veins by operation alone. When the injection treatment became popular this was for some time employed exclusively. To-day a combination of both operative and injection methods is current practice—a practice discussed at length in two recent papers.^{1,2} In 1932, when the Hutchinson Memorial Clinic of Tulane University was first opened, varicose veins of the lower extremities were treated entirely by the injection method, but with many disappointing results. The injection treatment is adequate for relatively small and isolated varices, but where there is incompetence of the valves of the veins communicating between the main deep and superficial systems—a fact which can be ascertained by a modified Trendelenburg test described in the papers referred to—injection should be combined with ligation. Of the varicose veins in 247 women 60 per cent. were associated with pregnancy; the other important factor in aetiology was heredity. In one series there were 57.5 per cent. of recurrences in patients who had received injections of sclerosing solutions alone, whereas there were only 18 per cent. of recurrences in those whose saphenous veins had been ligated and divided at the fossa ovalis in addition to having the veins injected.

PROGRESS IN PAEDIATRICS

Edited by Professor I. A. Abt with the help of Dr. A. F. Abt, *The 1937 Year Book of Pediatrics*³ presents a valuable summary of progress in many directions in disorders of children. Readers of earlier volumes in this series will be glad to learn that the editorial comments are continued and are as concise as ever. For example, after a very fair presentation

¹ *Surg.* 1937, 2, 389.

² *Ibid.*, 903.

³ Chicago: The Year Book Publishers. London: H. K. Lewis and Co., Ltd. (10s. 6d., postage 6d.)

of the papers published on the subject of the treatment of whooping-cough, the editor remarks: "The use of ascorbic acid in treatment of whooping-cough reminds us that nearly every newly discovered remedy in ancient and modern times has at one time been advocated for treatment of this disease." This indicates the type of approach made, and it is a matter for regret that there is not more "Abt" and less of what other people think. Random sampling and a study of the index indicate that contributions from the British Isles are few in number, which is either a mild injustice or a mild reproach for poverty of material. In either case paediatricians in this country should not let this prevent them studying the work set out, which represents in main the current paediatric practice of the North American Continent.

TUBERCULOSIS IN CYPRUS

An account of the mission to Cyprus of the National Association for the Prevention of Tuberculosis has already been given in this *Journal*, on July 3, 1937 (p. 30). A fully documented report⁴ by Dr. Noel Bardswell, the special commissioner appointed for the purpose, has now been issued. The difficulties met with in conducting the inquiry into the incidence of tuberculosis in this backward island are well brought out. The methods adopted consisted of personal questioning, physical examination, and Moro-testing of samples of the population in various districts. 8,084 children in villages and 1,841 in district towns were tested; 6.5 per cent. were found positive in the villages and 8.2 in the towns. Dr. Bardswell concludes that the problem of tuberculosis in the island is not as grave as had been generally believed here. The report is also of interest in that it furnishes a good description of the mentality, habits, and living conditions of the inhabitants. Dr. Bardswell is continuing his investigations, and hopes to lay down a scheme which will bring the disease under control. The work is of value not only in providing data of the disease in Cyprus but also in giving an opportunity to study the spread of tuberculosis in a primitive community.

We regret to announce the death on Wednesday morning of Sir Raymond Crawford, consulting physician to King's College Hospital and registrar of the Royal College of Physicians of London.

⁴ *Tuberculosis in Cyprus. An Interim Report on its Incidence and Means of Control.* By Noel Dean Bardswell. London: Adlard and Son. (2s. 6d.)

Under the editorship of Dr. E. Arnold Carmichael the *Journal of Neurology and Psychopathology* resumed publication in January last with the new title of the *Journal of Neurology and Psychiatry*. The demand for this special publication of the British Medical Association has exceeded expectations, and at the moment it is out of print. Arrangements have been made, however, for the reprinting of a limited number of copies. Intending subscribers should make early application to the Secretary, B.M.A. House, Tavistock Square, W.C.1, to ensure the receipt of the January issue, the first number of a new volume.

PERIPHERAL NERVE PAIN OF VERTEBRAL ORIGIN

Advances in the technique of radiography have made it clear that disorders of peripheral nerve function are often due to minor abnormalities or disease of the vertebral column. The work of Schmorl and his colleagues in Dresden, fully described in Beadle's monograph, has demonstrated the importance of lesions of the intervertebral disks in this connexion. The peripheral nerve pains which are a feature of the premonitory stages of ankylosing spondylitis, and which appear before any bony change can be detected, are without doubt due to irritation of the nerve roots in the region of the foramina. Hilton Fagge¹ described a plastic exudate enveloping the vertebral bodies, and it seems clear that the inflammation which precedes the calcareous deposition will affect the nerve roots in this part of their course. The pains become less severe as the inflammatory tissue gives place to bone, and it is rare at this stage for the foramina to be encroached upon. Nathan² studied the development of epidural and peri-radicular exudation in ankylosing spondylitis and by experiments upon dogs; he demonstrated that such exudations occurred in the early stages of the disease, and gave rise to sensory alterations of root distribution. Bechterew noted peripheral pains as a conspicuous feature in his cases of spondylitis of a different type, but in these cases there was meningeal inflammation, which appeared to spread to the cord itself. In spinal osteoarthritis there is no inflammatory stage. In this condition Garcin and Deparis³ noted that the peripheral nerve symptoms were often on the opposite side to that on which x rays revealed the presence of osteophytes. They suggested that this might be due to osteophytes in the course of formation and not yet opaque to the rays. Study of the changes which take place in the disks indicates, however, that the symptoms are less likely to be produced by the actual pressure of osteophytes, though this may occur, than by the narrowing of the foramina, which is the result of compression and thinning of the disk, and allows the vertebral bodies to come closer together. The presence of an osteophyte may lead to the compression being greater on the opposite side by leading to uneven thinning of the disk—this seems to offer a more probable explanation than that given by Garcin and Deparis. Peripheral nerve pains from such a cause are more likely to arise in the distribution of the lower cervical and lumbar roots since these roots almost fill the foramina. That sciatica is often the result of narrowing of the foramen of the fifth lumbar nerve root is well known, and brachialgia is sometimes due to a similar condition. Alterations in the shape of the vertebral bodies are often seen in profile radiographs of the cervical spine and may be secondary to changes in the disk or be due to trauma or infection. They are commonly associated with pain in the peripheral distribution of the cervical roots and even give rise to precordial pain

of anginal type. Actual subluxation sometimes occurs, and this is a serious risk in manipulative procedures in unskilled hands. Osteophytes are most frequent in the regions of greatest mobility—namely, the cervical and the upper lumbar region—and probably arise from intermittent tension on the lateral ligaments as a result of the increased mobility between adjacent bodies due to thinning of the disks. To describe these conditions the ugly and unnecessary term "discogenetic" disease has been coined by Albert Oppenheimer⁴ in an article which contains some interesting observations on narrowing of the intervertebral foramina as a cause of pseudo-rheumatic pain. He has, however, given credit to certain writers for originality of observations which had been made by others at an earlier date. It is not uncommon for credit to be given to radiography for discoveries made by the great clinicians of the past and now forgotten. It may be worth while to observe that even when radiography shows gross abnormalities peripheral-nerve pain may result from some other cause; careful clinical examination should therefore never be neglected.

B.C.G. VACCINATION IN CALVES

The favourable results obtained by Stanley Griffith, Buxton, and Glover⁵ in the experimental immunization of calves with B.C.G. find confirmation in a fully documented report⁶ from the Istituto Vaccinogeno Antituberculare of Milan, directed by Professor Ascoli. The investigation dealt with a total of ninety-four calves, and the immunizing effect of virulent human bacilli, living B.C.G., killed B.C.G., and killed virulent human bacilli, administered either subcutaneously or intravenously, was tested against subsequent infection with virulent bovine bacilli. This infection was carried out either by administering a culture or by allowing the calves to cohabit with tuberculous cows. In the latter case two sets of experiments were done: one group of calves were allowed to live with the tuberculous animals immediately after vaccination, another only after an interval which allowed for any immunizing effect to be established. The results obtained may be summarized as follows. Intravenous and subcutaneous vaccination with B.C.G. or with human bacilli appreciably increased the power of resistance, which prevented the development of tuberculous lesions in calves injected later with doses of virulent bovine bacilli that caused rapid death of all the controls from miliary tuberculous pneumonia. Repeated vaccination improved these results, but immunity was not obtained against ten times the lethal dose. Vaccination with bacilli killed by heat, even if repeated, never under the same conditions prevented the development of tuberculous lesions, although it increased the survival time of some of the calves; the same treatment did not protect them from natural contagion, nor did various modifications in administering the dead bacilli. Calves vaccinated intravenously with killed bacilli, when no

seat of the rupture. As a rule there is no immediate haematoma, though a measure of this will develop in accordance with the extent of muscle and vessel injury. The large haematomata associated with direct injuries are seldom if ever seen.

TREATMENT

In the case of a partial rupture of the calf muscles, unless very severe, the treatment can be on ambulatory lines. The foot is placed in the plantar-flexed position and elastoplast or adhesive strapping applied from the calf down to and including the sole of the foot. A firm bandage over all will stabilize the application. After a few days the patient is allowed to walk with the strapping in place and the heel of the injured side elevated half to three-quarters of an inch so as to keep the muscle relatively relaxed, the foot being in the position of talipes equinus.

The more serious condition of rupture, partial or complete, of the tendo Achillis, which arises in a similar way, is dealt with in a previous section. The condition has also been observed in the rectus abdominis, occasionally in healthy people and as a complication of tetanic spasms. In rare cases the muscle has undergone a degeneration which makes it abnormally brittle. The treatment is on the lines laid down above. I do not think that operative treatment is of any value unless the rupture has been through a tendinous part of the muscle.

RESTORATION OF FUNCTION

Whatever the extent or cause of the primary injury to a muscle some degree of disability immediately results. Treatment directed to the restoration of full function should be based on similar lines for all cases, the severity of the injury determining the time required for complete recovery. Light massage a few days after injury will be comforting and will assist the absorption of minor haematomata. Massage in the presence of larger haematomata is unsound. Subsequently the use of the injured muscle by graded exercise is the most effective means, and the degree to which this is pressed will depend on the extent of the primary injury. In severe cases, and for those patients who are little inclined to help themselves, the use of gentle faradic stimulation will be helpful. This should not be employed until the haematoma has been absorbed and the repair process is well advanced—normally two or three weeks after the more serious injuries. Other physiotherapeutic measures are advocated, but, though mostly harmless, they play a very secondary part compared with graduated voluntary exercise in restoring the full use of the injured muscle.

Strains

An initial strain may rupture a few fibres at a muscle tendon junction or insertion. If the initial injury is not treated conservatively subsequent use of the muscle before it is restored to normality may result in a chronic effusion at the site of injury which causes pain from the tension produced by contraction of the muscle. Calcification or ossification is sometimes observed in the strained tendon. This condition is most often seen in the origin of the adductor muscles, and occasionally develops in the origin of the common extensor of the forearm and in the insertion of the deltoid muscle.

Treatment should be directed towards sparing the muscle involved from severe stress for a few weeks, while maintaining its condition by faradism and gentle exercise. Local treatment of a counter-irritant character is not often effective. In some cases the presence of focal sepsis may

be a cause of the continued irritation. The removal of dead teeth or other source of toxæmia may clear up the trouble.

Myositis Ossificans

This is a condition in which bone is formed in the substance of or immediately deep to a muscle. Its appearance is usually secondary to an injury which allows bone-forming cells to penetrate the haematoma of a muscle injury. It is most commonly seen as a complication of fractures and dislocations in the elbow-joint region. It is also observed from time to time in relation to the central part of a long bone, but for some reason it is relatively uncommon in this situation. It may also occur without a gross bone injury. This is seen in the thigh following a severe kick or even after the too firm application of a tourniquet. The result of this bone formation may be to limit the movement of the neighbouring joint either by muscle fixation, as is seen when the quadriceps is involved, or, by forming a bony block, checking movement by contact with the neighbouring bones, a state not uncommon about the elbow-joint. The condition itself is painless unless movement is roughly forced, but it may interfere very seriously with the function of the limb.

TREATMENT

In a case in which the irregular bone has recently formed complete rest of the part is essential. This is best procured by fixation of the affected limb in plaster-of-Paris. In the course of a month or so this usually leads to absorption of the unwanted bone. Forced movement will continue to irritate the new formation, preventing its absorption and even causing increase in its bulk. The period of rest necessary for complete absorption varies considerably, and is shorter in children than in adults. In the latter one may have to wait as long as six months before attempting to restore function. Operation for the removal of bone tissue is only justifiable when the condition has existed for a year or more, and when a definite formation that is blocking joint movement is present.

Volkman's Ischaemic Contracture

Though Volkmann's contracture is not primarily an injury of muscle, reference may be made to it here on account of its clinical importance. It is due to an interstitial fibrosis of the muscle which follows necrosis of greater or lesser amounts of muscle tissue from ischaemia. The condition is initiated by depriving muscle of its blood supply, partially or completely, for a relatively short time. The mechanism by which this temporary anaemia is brought about is usually a tight application of splints over an unreduced fracture. Occasionally a progressive effusion of blood beneath the fascial plane may produce the effect. It would seem that tourniquet pressure seldom, if ever, has the same result. At times partial or complete interference with the nerve supply to the part complicates the issue. For practical purposes the condition is met with in the flexor muscles of the forearm, and is most commonly noted after a supracondylar fracture in childhood. Some authorities state that the condition is never seen in the adult—a statement true only of the more severe form.

TREATMENT

It is quite clear that prophylaxis is of the first importance. In fractures in the region above mentioned subfascial tension must be avoided or relieved as soon as possible. In the application of any rigid fixation to the arm there must be no undue tension, whether it be by bandage, splint, or bone pressure on major vessels. The

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation.

TREATMENT OF MUSCLE INJURIES

BY

C. MAX PAGE, F.R.C.S.

Minor isolated injuries to muscles are commonplace, but on account of the elasticity of structure of these organs such injuries are seldom the source of serious disability. When the trauma is more severe other structures will very likely be damaged as well. For example, in most fractures of long bones some laceration of the overlying muscles is necessarily involved. In severe contusions of the abdominal muscles the underlying viscera may be damaged. In these examples consideration of the muscle injury is a secondary matter. The repair of cut or torn muscle is effected by the formation of fibrous tissue from the granuloma formed in and about the primary exudate of blood and serum. Reproduction of new muscle fibre does not occur. When repair by fibrous tissue formation is complete the function of the injured muscle is rapidly restored by normal use if the separation of the fragments has not been excessive.

For the purposes of this contribution muscle injuries may conveniently be divided into four groups—namely: (1) open wounds (cuts and missile wounds); (2) direct injuries (closed)—contusions and ruptures; (3) indirect injuries—ruptures in long-bellied muscles; (4) strains—localized minor injuries at muscle insertions or muscle-tendon junctions. In addition myositis ossificans and ischaemic contracture are touched on, though properly these do not come within the scope of the present series.

Open Wounds

Damaged muscle and muscle haematoma form a favourable bed for the development of anaerobic infection. An immediate and careful wound excision under anaesthesia should therefore be carried out in any instance in which there is a suspicion of serious bacterial contamination in wounds involving muscle. The excision or débridement should be effected not later than twelve hours after injury. Antiseptic lavage is a poor substitute for the above method unless it be employed very soon after the event and the wound happens to be clean-cut and freely open.

No attempt should be made to suture muscle or tendon at the primary operation in any case where serious contamination is probable. As a secondary procedure when the wound is healed it may occasionally be worth while, especially when tendon has been involved. Prophylactic injection of anti-tetanic serum and anti-gas serum should be given if earth or faecal contamination is suspected. In case of spreading infection from the primary wound the general principles of wound treatment should be applied. Once infection is past and the wound is healed restoration of function should proceed on the lines laid down below.

Direct Injuries (Closed)

Contusions and closed laceration of muscle result commonly from kicks sustained at football. The immediate treatment will be to apply a firm strapping or bandage to support the injured part and to limit the effusion of blood. In practice these injuries must often affect the gluteal and thigh muscles, and effective support

in those situations is not very easily applied. An adhesive elastic bandage is usually most effective. A few days after the injury gentle massage may assist the absorption of the smaller bruises. If the injury is more extensive a longer period of rest is advisable; a definite haematoma will probably form, and massage of this will serve no useful purpose, and indeed may be harmful by renewing haemorrhage and delaying the repair process.

MUSCLE HAEMATOMATA

Small haematomata, if rested, will be absorbed in a week or so, and treatment to restore function can then proceed on normal lines. Large haematomata as met with most commonly in the gluteal region or thigh are best left untouched for ten to fourteen days or even longer. The clot will by then have shrunk down, leaving a serous cyst. At this stage evacuation by aspiration or through a stab incision will expedite the healing process. If the haematoma is not evacuated a blood cyst will probably form and will be slow to absorb, and the restoration of function will be correspondingly delayed. Suppuration occasionally occurs in a neglected haematoma. Evacuation of the pus by incision is then called for. Drainage, if employed, will be necessary only for a day or so.

Complete rupture of a muscle from direct violence is uncommon. The rectus femoris is the most often affected. A wide gap is formed, and suture of the torn ends may seem the proper procedure. In my experience the attempt is of no value unless the tear is in tendon or at the insertion into bone—for example, in the tendo Achillis or at the quadriceps insertion into the patella. In these cases, due nearly always to indirect violence, prompt suture is good practice. When a fleshy part of a muscle is ruptured repair by fibrosis occurs, and though a permanent alteration in the form of the muscle may be caused, little interference with function will ensue.

Indirect Injuries

Rupture of contracting muscle by its own force occurs as a rule in the muscular middle-aged taking unusual exercise, but sometimes in a relatively young man as a result of sudden severe physical effort. Some individuals are peculiarly liable to ruptures of this kind, and must be regarded as brittle-muscled. The commonest seat of these injuries is in the calf of the leg; the rupture may involve any part of this from the tendo Achillis to a few fibres in the gastrocnemius. At the time of the injury the patient feels as though he had been hit in the back of the leg with a stick, and he very likely falls to the ground. The hamstrings may be similarly affected, but the injury is not as a rule so disabling in its effects. In the case of the long head of the biceps cubiti the tear is usually in the tendon and in that part which passes through the shoulder-joint. The injury generally occurs in association with osteo-arthritis of the joint, the disease process having caused some disintegration of the tendon. The injury leaves an unsightly arm but much less disability than might be expected. Suture of the tendon to the biceps groove is worth while in a youngish man.

The diagnosis in these cases is made by the history associated with the presence of localized tenderness at the

THE TREATMENT OF DIABETES

SECOND LETTSOMIAN LECTURE

In his second Lettsomian Lecture, delivered at the Medical Society of London on March 2, Dr. GEORGE GRAHAM continued his survey of the changes and results of treatment of diabetes in the last fifteen years. A report of the first lecture appeared on March 5 (p. 529).

Dr. Graham said that the majority of the patients whose disease was severe enough to require insulin were easily controlled. The blood sugar could be kept within normal limits and the urine never contained sugar or acetone bodies. Some of these patients never had hypoglycaemic attacks, or, if they did, the attacks were mild and easily recognized and caused no real inconvenience. The condition might tend to improve so that in some cases the insulin could be abandoned, or it remained stationary, but the patient was liable to temporary upsets which could be traced to specific causes like illness or injury. If the dose of insulin was increased sufficiently as soon as possible after glycosuria and hyperglycaemia occurred, the diabetic condition might not be made worse and the dose of insulin might be decreased again to the original level. The dose of insulin required by patients of this type might be very large.

So far he had spoken of the disease which got better or remained stationary, but there were unfortunately many cases in which the disease progressed. This might occur early in the history or, on the contrary, after the disease had taken a mild course for several years. The patient might pass sugar before one or other or both doses of insulin, and when the dose of insulin was increased to prevent the hyperglycaemia he might suffer from hypoglycaemia either at midday or during the night. The condition bore no relation to the size of the dose of insulin, for the symptoms might occur with quite small doses or with large. The action seemed to be due to two factors: (1) the insulin acted more quickly so that the blood sugar rapidly decreased; (2) the effect of insulin on the blood sugar no longer lasted ten to twelve hours, but only eight to ten.

Insulin Resistance

An important type of case was that which was known as "insulin-resistant." In extreme cases of this kind very large amounts of insulin were given without producing any effect on the blood sugar. Thus Miller and Heimak gave 300 units, then 500 units, and finally 1,000 units a day, and in spite of this the patient died in coma. Root gave 525, 840, and finally 1,680 units in the last three days of life without preventing death in coma. Both these patients had haemochromatosis, and the liver was practically destroyed. In the less severe cases 200 to 400 units might be required before any effect was produced. Dr. Graham related certain observations of his own which he said suggested that some interfering substance was present which neutralized the insulin, but that the usual effects were obtained if sufficient insulin were given. The liver appeared to play some important part in the insulin-sugar mechanism.

Insulin Tolerance

It was important to consider what was happening to a healthy person who could tolerate 100 units a day without developing hypoglycaemia. Did he have to produce this amount of insulin over and above that which an insulin-sensitive subject required? Or did he produce the same amount because there was no difference between the indigenous insulin and that injected? Further, what would happen to this man if he developed diabetes? Would he straightway require more than 100 units before the blood sugar could be controlled? Dr. Graham

answered this question by relating a case which had puzzled him profoundly, and from this case and another he deduced that when a healthy person who could take 25 to 100 units of insulin a day without having hypoglycaemia developed diabetes he would need large amounts of insulin before the diabetes was controlled, and that the amount of insulin was not a certain guide to the severity of the diabetes. If the patients improved they would not have overdoses, but would continue with their large dose of insulin although it might now be unnecessary. The diagnosis could be made by reducing the insulin by 8 units a day and watching the blood and urine tests. If the patient still needed insulin the blood sugar one hour after a meal would rise above 180 mg. and glycosuria would occur. In such a case the doses of insulin should be increased at once. If the diabetic condition had recovered the blood sugar would not rise and glycosuria would not occur. The patient could then safely leave off insulin provided that the urine passed after the evening meal was tested regularly for sugar. He did not suppose there were many of these patients who were taking large doses of insulin which they no longer needed, but the possibility should be remembered.

Changes in Treatment

The most important change in treatment from the point of view of the patient's comfort was the great improvement in the diet. Diets before the Allen regime were very unpleasant owing to the necessity for eating a very large amount of meat and fat, together with the various diabetic foods. The latter contained little or no carbohydrate and were unpleasant and unsatisfying. The change from these high protein and fat foods to the low protein and low fat diets was a great relief to the patient. The "hunger day" was of value and easily tolerated by most patients, although some found it irksome. If it was repeated at very frequent intervals in the attempt to keep the blood sugar normal the patients usually found it almost intolerable. Insulin made it unnecessary to have any more "hunger days," but the improvement in the health of the patient, who had been kept alive with severe dieting, was so great that the diet was at first little altered. It was not until 1926-30 that the idea became prevalent that carbohydrate should be increased. High carbohydrate dieting was now largely used, though there was still a good deal of controversy over the amount of carbohydrate and fat which should be given. The average carbohydrate of the diet in his cases was 150 grammes, but it had a tendency to increase. He had the impression that at least 100 grammes of carbohydrate should be given, and if the patient could not take that amount insulin should be given and the carbohydrate raised to at least 130 grammes. Many patients, especially women over 60, did not wish to eat more than this amount. Young patients needed much more, and to them he was giving at least 150 grammes and increasing it to 200 or 230 for growing children. One of the complaints of diabetic patients, and especially of the women, had been the poorness of the tea meal, and an advantage of the new slow-acting insulins was the improvement which could be made in that meal.

The mortality rates of his patients had decreased since 1932, coinciding with the great increase in the carbohydrate of the diet, and he believed that the extra carbohydrate had improved the health of the patients so much that they were able to withstand illnesses like pneumonia and influenza and make good recoveries.

The other great advance had been made in the analysis of the foods and in the use of food-value tables. For the latter in this country a debt was due to the late Dr. Otto Leyton, who realized that English patients could not use food tables easily in which the amount of food was expressed as a percentage. Leyton thought that if the amounts of food which contained 5 grammes of

danger signals are a dusky blue appearance of the hand on the injured side and obstruction of the normal radial pulse. When these are observed action should be prompt either to relieve pressure of bandages and splints or to rectify the position at the seat of fracture.

Once the condition of fibrosis and contracture is established, it may, if not too severe, be considerably improved by graduated stretching of hand and wrist by suitable splintage. Various operative treatments have been devised for the more severe forms, but a consideration of them hardly comes within the scope of this article.

HEALTH OF THE NAVY

The report on the health of the Navy for 1935 (H.M. Stationery Office, 2s. 6d.) records a further decrease in the incidence of disease and injury. The America and West Indies Station showed the lowest sick rate. Improvement is especially noticeable in the incidence of diseases of the respiratory system. In 1935 there were 1,279 cases, in 1934 1,526, and in 1933 3,494. The causes of death in this group during the year under review were bronchopneumonia 5, gangrene of the lungs 1, and mediastinal abscess 1.

Infective Diseases

Despite the concentration, during the last quarter of the year, of large numbers of men at bases in the Eastern Mediterranean, where bacillary dysentery is prevalent, the increase in the case ratio for this disease was only very slight. From the China Station twenty-three fresh infections of dysentery are recorded. Ten of these were amoebic, and the report states that the favourable impression formed of the value of carbarsone (Lilly) in the treatment of amoebic dysentery was further confirmed. In several cases intercurrent tachycardia, attributed to emetine, was noted. Only nine cases, five of typhoid and four of paratyphoid, occurred in the enteric group, and this small incidence among so large a number of men at risk all over the world may be regarded as a tribute to modern preventive medicine.

One case of filariasis was returned by H.M.S. *Achilles* (Home Fleet). The infection was traced to previous foreign service in the Yangtse Valley. For three years the officer affected had suffered from recurrent skin conditions resembling erysipelas or cellulitis with lymphangitis. The diagnosis was ultimately confirmed by the finding of *Filaria loa* in his blood at midnight. The single case of leishmaniasis recorded also occurred on the Home Station. The officer affected had recently returned from the Persian Gulf. Oriental sores appeared on the right arm and left leg, and Leishman-Donovan bodies, intracellular and extracellular, were demonstrated. A course of intravenous injections of sodium antimony tartrate effected a complete cure.

The report records a decrease in the number of cases of malaria from 255 in 1934 to 180 in 1935. The East Indies Station again returns the highest incidence, although its ratio per thousand is more than halved. The largest number of cases in any one ship was twenty-two in H.M.S. *Endeavour*. The cases occurred during a two-months survey of the islands north of Penang. Prophylactic quinine was taken daily, but frequently parties had to spend the night ashore in camp. With regard to treatment a single course of atabrin, followed by plasmoquine, was administered to all cases at the R.N. Hospital, Hong Kong. In Ceylon, however, it is stated that the newer remedies proved disappointing, especially as regards the relapse rate, and reliance was placed on intramuscular and oral quinine.

Schistosomiasis japonicum

All of the twelve ratings whose infection with this disease at Chinkiang on the China Station was described in the previous report¹ were kept under observation during the

following year, but no positive findings of ova were notified. The most severe of these cases, however, a stoker aged 30, showed signs of damage to the pyramidal tracts and involvement of the higher centres. After a long course of hospital treatment at Hankow, Hong Kong, and Chatham, he was finally invalided out of the service. Only one fresh case of this disease was reported in 1935. This case is of unusual interest. While serving in the Home Fleet an officer, aged 30, had an epileptiform attack in the wardroom of his ship; another attack followed two days later. This officer had returned from three years' service in China in 1933, but he gave no history of tropical disease. A third seizure occurred a week after his admission to Haslar Hospital. Each attack was preceded by a feeling of "weight and tenderness" over the left parietal region and by a temporary "black-out" of vision. Examination revealed a small paracental scotoma in the inferior temporal quadrant of the left field. A provisional diagnosis of cerebral tumour in the cortex of the left temporo-parietal region was made. Operation revealed a firm yellow spherical tumour, about one inch in diameter, and fairly sharply demarcated from the surrounding brain tissue. This was removed, and subsequent examination showed it to be made up of the ova of *Schistosomum japonicum*. Although a temporary paralysis of the right arm and difficulty in speech followed the operation the patient eventually made a good recovery and returned to duty.

TUBERCULOSIS ASSOCIATION AT OXFORD

The annual provincial meeting of the Tuberculosis Association will be held at the Dunn Laboratories, Oxford, from April 7 to 9. Accommodation for a limited number of men will be available at Exeter College; ladies and those who do not wish to have rooms in College should make early application for hotel accommodation. The charges (exclusive of a 10 per cent. tip to be added to the bill) are as follows: for all meals, including the annual dinner and accommodation in College, £2; for lunch and dinner but no accommodation in College, £1 5s.; for the annual dinner with wine, 11s. Those who do not take wine should deduct 4s. from these amounts. Meals and accommodation are from midday Thursday to midday Saturday, including lunch on both days. Members of the Tuberculosis Association should send cheques for the amounts to Dr. F. R. G. Heaf, Manson House, 26, Portland Place, W.1, by March 31, when the tickets will be sent to them. Guests may be invited on these terms. On the first day of the annual meeting papers will be read on the incidence of tuberculosis in young adult women, with special reference to employment, and later that afternoon problem cases will be discussed by Professor Girdlestone, F.R.C.S., and Dr. W. Stobie. It is suggested that an entertainment should be held in the evening. During the morning of April 8 papers will be read on extra-pleural pneumothorax, and what can be done to prevent the tuberculous patient from relapsing. In the afternoon visits will be paid to the Wingfield Morris Hospital and the Osler Pavilion, where tea will be taken. In the evening the president's reception will take place at Exeter College, followed by the annual dinner. On the morning of Saturday, April 9, papers will be read on the progress of radiology by Dr. Felix Fleischner of Vienna and others, and at 12.30 p.m. the annual meeting of the association will be held. Further information may be obtained from Dr. N. England, 1, Becket Street, Oxford.

It was decided at a recent meeting of the Oxford Graduates' Medical Club to extend the membership to all medical graduates of the University of Oxford and to abolish the subscription to the club. The secretaries are anxious to make the list of members accurate and complete, and would be glad to receive the names and addresses, with details of colleges and hospitals, and the date of taking the B.A. degree, from those who become members of the club under the new constitution.

¹ See *British Medical Journal*, October 10, 1936, p. 726.

cause of aerophagy was a different one. Any epigastric or substernal discomfort would almost certainly result in aerophagy as an attempted mechanism of relief. The trouble was that, like every habit spasm, it tended to go on after the cause had disappeared, and thus what was at first a purposive act became a tic. Having decided as to the mechanism, what was the obvious treatment? In the first place, the cause must be investigated with the greatest care. There were obvious causes like gastric ulcer or cancer, cancer of the oesophagus, and so on, but there were much less obvious causes, such as the early phase of angina pectoris, or some of the earlier manifestations of cirrhosis of the liver. To correct the deficiency, meals should be taken more leisurely, be relatively dry, salivation might be checked in certain cases by administering belladonna, and the rather sensitive nervous system treated by small doses of sedatives. What should not be done in aerophagy was to administer carminatives.

So much for aerophagy. Of the second group—delays and obstructions in the stomach and bowel—responsible for flatulence, these were very largely surgical conditions such as cicatricial stenosis in the stomach, giving rise to pyloric stenosis. A diverticulitis affecting the ascending colon was not an infrequent cause. Delay in the passage of food down the alimentary tract might be associated with spasm, and spastic colon was a cause of intestinal flatulence. It could also be associated with atony of the gut, and atonic constipation was again a not infrequent cause. The treatment of delays and obstructions must in the first place be directed towards the underlying lesion. The third group, consisting of fermentative activities in the gut, was a rather difficult field because so little was known of the subject. Two main types had been differentiated, one that of intestinal carbohydrate dyspepsia, and the other the cases occurring in intestinal affections in which there was excessive protein putrefaction. In the case of intestinal carbohydrate dyspepsia cereals should be avoided, also root vegetables, and in the protein forms of flatulence a lacto-vegetarian diet should be imposed. The fourth factor was a disturbance of the circulation in the intestinal wall. This was a factor not yet adequately assessed. The fifth factor was damage to the intestinal mucosa, not from toxins which arose in such diseases as typhoid and dysentery, but rather from poisons which one took optimistically and called purgatives and which undoubtedly irritated the mucous membrane of the stomach and intestine and promoted considerable interchange of gases and toxins which would not otherwise be allowed to pass through.

The treatment of any condition had not only to overcome the causes but to deal with symptoms. There were three main ways of dealing with symptoms: (1) the administration of carminatives; (2) the administration of absorbents such as charcoal and kaolin, neither of them a very effective remedy; and (3) particularly in post-operative flatulence, the passage of a tube for the removal of the gas.

Surgical Considerations

Mr. C. W. GORDON BRYAN thought there was a danger of being unduly impressed by the nervous or functional element in these cases and overlooking the organic causes of partial obstruction which could be removed by surgery. This applied especially to early or partial obstruction of the ascending or transverse colon where flatulence was commonly a permanent symptom. One problem in great need of solution was how best to treat cases of so-called visceroptosis of various types. In many of these cases the element of mechanical obstruction seemed to be important, the result of the congenital bands and membranes that were so common about the ascending colon and right half of the transverse colon. A large measure of relief could be given by freeing the colon as the result of a thorough removal of these bands, but he would not advocate wholesale operations on the neurasthenic, tired, thin young woman, usually suffering from an anxiety

neurosis, who had a dependent caecum and complained of a dragging or spasmodic pain when fatigued.

Passing to the difficult subject of post-operative flatulence and the more serious difficulties of mechanical and paralytic ileus, Mr. Bryan said that the causes of these dangerous conditions were of importance because the surgeon should be able to do so much to avoid them. In the great majority there was an element of mechanical obstruction, and true paralytic ileus was very rare. He briefly mentioned the measures which seemed important to him in the treatment of post-operative paralytic ileus. These were: (1) rest and avoidance of stimulants; (2) continuous siphonage of duodenum by a tube passed through nose or mouth; (3) repeated administration of anti-gas-gangrene serum; (4) continuous application of heat to the abdomen; (5) administration of a spinal anaesthetic; (6) the giving of large quantities of fluid. Continuous intravenous methods were sometimes the best, but often the giving of large quantities of normal saline subcutaneously was the simplest and most practical means. The simplicity and value of this method and the large quantity of fluid that could easily be given were perhaps not generally realized. On the question whether morphine should or should not be used he had an open mind. He preferred to avoid it, because he thought it caused vomiting. Although it might not increase distension, it did tend to prolong it.

General Discussion

Sir ARTHUR HURST was surprised that Professor Cohen had not referred to the gall-bladder as one of the most common causes of so-called gastric flatulence. The individual with cholecystitis had an uncomfortable feeling in his epigastrium which he misinterpreted as due to the presence of gas. As there was no wind to bring it away he made futile efforts which manifested themselves in swallowing air. With regard to adhesions, he believed that these very rarely accounted for the chronic uncomfortable abdomen and flatulent dyspepsia. He had seen many patients who had had operations for adhesions and had never been the better for them. Only twice had he found it necessary to advise operation for diverticulitis. Even in severe cases where obstruction was present it was nearly always possible to overcome it by medical means and to keep a patient well afterwards. He did not agree with Professor Cohen's depreciatory remark about charcoal.

Dr. A. H. DOUTHWAITE spoke of the post-operative flatulence which was so troublesome to those who had undergone an abdominal operation. He believed that a good deal of it was due to the post-operative treatment. It was worse years ago when it was customary to purge these patients and starve them for twenty-four hours before operation. In certain cases patients, either owing to the advice of their surgeons or to their own obstinacy, refused to follow the usual practice of living on a fluid diet for a day or two after an abdominal operation, and took some solid food. These patients never stopped from having flatulence.

Mr. ZACHARY COPE said that one subject which had not been dealt with was the class of case in which extreme distension accompanied renal disease. This was not due to any of the causes Professor Cohen had outlined. He held that it was in some way a reflex phenomenon. The same was true of gall-bladder trouble. He had seen the most extreme distension with biliary pain without much peritonitis. He had sometimes been tempted to open the abdomen, thinking the large bowel was obstructed, and in one or two cases he had actually done so, but had found nothing except the gall-bladder disease, and perhaps some local inflammation, but no general inflammation. He thought it possible that here they were dealing with a reflex phenomenon of the large bowel.

Dr. MAURICE SHAW was rather disappointed that Professor Cohen, while stating that carminatives were useful

carbohydrate were calculated patients would exchange their foods much more easily, and accordingly Harrison and Lawrence extended this system, and in 1930 Lawrence and McCance re-analysed many foods and thought that certain fruits contained less carbohydrates than was supposed. Their investigation was continued by McCance and Widdowson, who repeated the work and found that the carbohydrate was more than had been thought. The changes made had been relatively slight, but he thought that a stable figure had now been reached. A large number of foods had been analysed, and patients had a considerable choice of foods and had no reason to complain of any restriction.

Nova et Vetera

BENEDICT ARNOLD, THE FIGHTING DRUGGIST

Commemoration of the 206th anniversary of George Washington's birth on February 22 recalls a striking personality with whom he was intimately associated at one period of his career. Benedict Arnold was born at Norwich, Connecticut, in 1741. Apprenticed to Donald and Joshua Lathrop, relatives of his mother, who owned the largest drugstore in the town and were also practising physicians, he picked up scraps of medicine and surgery. At the age of 21 he opened a shop of his own in New Haven, in those days a trading village of some five thousand inhabitants, having previously made several voyages to the West-Indies and to London to buy drugs, books, and stationery. Over his store he put up the modest sign "B. Arnold, Druggist, Bookseller," with the motto "Sibi Totique." Business was successful from the first, and for thirteen years he was a leading and respected citizen of the community. At the outbreak of the American Revolution the "fighting druggist" left his shop for ever, organized a company of sixty volunteers, and started out for combat. His picturesque and heroic adventures have made his name almost as familiar in his country as that of Washington. One of his most celebrated feats is his march through the uninhabited Maine forests against Quebec, which for hardship and endurance is probably unparalleled in American history. At the Battle of Saratoga Arnold was the true hero, but Horatio Gates, apparently jealous of his fame, called him off the field, refusing to give him credit for a victory which marked the turning-point in the Revolution. This treatment embittered the proud and ambitious Arnold. And then Congress had promoted five junior officers over his head, in spite of Washington's protest. Next year we find him opening treasonable correspondence with Sir Henry Clinton, Commander-in-Chief of the British troops. Two years later he accepted the post at West Point with the intention of betraying this stronghold to the enemy. If he succeeded his reward was to be £20,000, and if he failed £10,000. Somehow the plot leaked out, and Arnold escaped to the British lines. He was appointed a Brigadier-General in the British Army and spent the remainder of his life in lonely and dishonoured exile in England and in Canada. He died in London in 1801. His story was told by William Abbott in the *American Druggist*, 1900, 36, 186, and his memory has recently been recalled by Clifford H. Rudes in the January number of the *Druggists' Forum*.

Reports of Societies

CAUSES AND TREATMENT OF FLATULENCE

At a meeting of the Medical Society of London on February 28, with Mr. J. E. H. ROBERTS in the chair, a discussion was held on the causes and treatment of flatulence.

Professor HENRY COHEN said that flatulence was one of the commonest of dyspeptic conditions, yet its mechanism was very little understood. Flatulence was a term often used by a patient in order to shield his own inability to describe his symptoms. Such symptoms as palpitation, nausea, constipation, headache, and cardiac pain were hidden in the usual complaint of flatulence. But "flatus" meant wind, and thus the essential symptoms must include wind or gas as an integral feature. There were five symptoms which might be complained of by a patient whose true complaint was flatulence. The first was belching or eructations; the second the passage of flatus per rectum in excessive amounts; the third a feeling of distension; the fourth gurgling or borborygmus; and the fifth pain or discomfort.

Flatulence could be defined as gas in the stomach or bowels, giving rise to discomforts which were relieved when the gas was expelled. The sources of gas in the alimentary tract were threefold: (1) swallowed air; (2) gas arising as a result of certain chemical changes; and (3)—a possibility, but not yet with certainty proved—the direct excretion of gases into the stomach and intestine from the blood stream. Four factors tended to modify the absorption of gas from the intestine. The first was the nature of the gas itself. Carbon dioxide was absorbed very rapidly, oxygen much more slowly, and nitrogen hardly at all. The first factor which tended to modify absorption, therefore, was the diffusion constant of the gas, and the second, the tendency of gas to combine with haemoglobin. The third factor was the diffusion of certain gases in the tissues themselves, and the fourth, the mucous membrane of the intestinal wall. If gases such as carbon dioxide and oxygen were absorbed into the blood stream, it was clear that any interference with the circulation in the gut would result in the accumulation of gases therein. This could be produced by any condition which caused venous stasis. Under normal conditions the amount of gas in the gut which was not absorbed was relatively small; its average composition was 10 per cent. carbon dioxide, 30 per cent. methane, and 60 per cent. nitrogen.

The Clinical Aspect

From the clinical standpoint flatulence might be divided into gastric and intestinal. Gastric flatulence was very largely the result of air-swallowing or aerophagy. Its most common symptom was a feeling of distension which was relieved by belching. Intestinal flatulence was much less commonly the result of aerophagy and much more commonly the result of fermentative processes. The division into gastric and intestinal flatulence was largely artificial, and it was far better to classify flatulence according to the mechanisms just described, although, of course, more than one mechanism might exist in any particular case. But the mechanisms described should enable certain types of flatulence to be recognized, and Professor Cohen considered each of five groups in turn.

The first of these was excessive air-swallowing or aerophagy. More air than usual might be swallowed because meals were hurried or mastication inadequate, or because there was excessive salivation, which last was responsible for the aerophagy in many post-operative conditions. Certain foods, such as omelettes and rusks, might, if taken quickly, carry more air into the stomach, and this was true of aerated water. But perhaps the commonest

In 1838 Johannes Müller, teacher of Schleiden, Schwann, and Virchow, in his work "On the Finer Structure and Form of Morbid Tumours," established the cellular character of new growths. This landmark in the history of cancer has been commemorated by the New York Academy of Medicine, when Professor Howard W. Haggard read a paper entitled "The Conception of Cancer before and after Johannes Müller."

frequent complication, but it was important when it happened.

Treatment he would divide into three stages, including as the first line of treatment the prevention of the development of the condition altogether. The patient should not be given excessive doses of morphine; the absolute minimum should be used both before and after operation. Any drug that was likely to interfere with the respiratory movements was better omitted. In addition to that, every effort should be made, at least in patients whose operation was not an emergency one, to see that their respiratory apparatus was in the best possible shape. It might be necessary to institute breathing exercises and general massage and movement. It was in the early stage that the inhalation of carbon dioxide gas was of particular value; in a later stage, when the bronchus was already obstructed and the condition established, it was a waste of time to give carbon dioxide. Unfortunately he did not know of any medicine that would help the patient to expel the block, but anything which made him cough and so assisted self-expulsion should be given. If he could not expel it himself the only thing to do was to expel it for him, and in that event bronchoscopy was required. He was entirely against bronchoscopy as a routine at the earliest stage, nor did he think more than one bronchoscopy necessary as a rule. When suppuration supervened it was in the form of either lung abscess or bronchiectasis. Postural treatment for most of these patients was out of the question. It was well to wait, encouraging the patient to cough up as much as possible, until the abdominal scar was safely healed, and then the bronchiectasis or the lung abscess could be treated on its merits.

Role of the Anaesthetic

Dr. E. H. RINK suggested that the term "massive collapse" should be restricted to the severest cases, and the terms "lobar" and "lobular atelectasis" be substituted for others. He believed that the anaesthetic in itself had very little to do with the primary condition of atelectasis. On the average he found that the proportion of chest complications after abdominal operations, including those for hernia, was about 14 per cent., while that for non-abdominal operations was about 1 per cent. It was natural to suppose that irritant inhalation anaesthetics would be a factor, and it was true that ether or any other anaesthetic if unskillfully administered would do harm. But there was no evidence that ether when perfectly administered played any important part in the production of atelectasis. At his hospital many hundreds of tonsillectomies had been performed under pure ether and oxygen anaesthesia, and there had not been a single case of post-operative atelectasis. At the same time, it was only common sense not to administer ether, unless unavoidable, to a bronchitic patient for an upper abdominal operation. Ever since the nature of this complication had been realized efforts had been made to avoid it, usually by the adoption of some single measure, such as the avoidance of all inhalation anaesthetics or the giving of large doses of atropine, for all cases. All these single measures were doomed to failure because the causation of atelectasis was multiple.

Atelectasis was commoner in men than in women in the proportion of about three to one. There were two reasons for this, one being that bronchitis was commoner in men than in women, and the other that men breathed primarily with their diaphragm and women primarily with their thorax. No age was exempt. Some severe cases occurred in children, but the frequency of chest conditions increased with increasing age. He believed that in every case of atelectasis careful inquiry into the history would show evidence either of chronic bronchitis or of something like the tail-end of the common cold. The consistency with which purulent or muco-purulent sputum was produced in these cases made it impossible for him to believe other than that the infection was already present latent

before the operation. With regard to pre-operative measures, breathing exercises for a week before an abdominal operation might be of great benefit. Provided the condition of the patient would warrant it, in bad cases requiring abdominal operations spinal or local anaesthetics should be used.

General Discussion

Dr. HORACE JOLLES described two cases which had been under his care during the last twelve months in which the atelectasis had been due to paralysis of the phrenic nerve following mediastinal pleurisy and a paralysis of the diaphragm. Dr. RANFORD WEST mentioned certain work on animals in connexion with the acute collapse which took place in curarine poisoning. Curarine, an active alkaloid of curare, could produce sudden collapse of the lung without any warning, and the post-mortem finding was one of complete general collapse. He drew attention by means of a diagram to certain similarities between the action of ether on respiration and of curarine.

Dr. LEONARD FINDLAY, remarking that he had had a considerable experience of spontaneous collapse in children, said that previous speakers had advanced no definite cause for post-operative collapse, but had brought in a multiplicity of factors. Therefore the causation of spontaneous collapse might have some relevance. The radiological picture in the average example of post-operative collapse was very different from that in the average case of spontaneous collapse. The sharp margin seen in spontaneous collapse was not observed in the other. If inquiry were made into the history of these cases of spontaneous collapse one would learn that a most inveterate cough was the initial symptom. That being so, he could not understand how it was said to be due to an obstruction. If some material getting into the bronchus was the cause, surely the complication would be most frequent after operations on the nose and throat, and yet there it was at its rarest. It occurred nearly always only after abdominal operation.

Mr. J. B. HUNTER said that it was not realized how greatly anaesthetic practice had changed. Some of them would remember the time when open ether was employed extensively. Atropine then came into use and had been used ever since, irrespective of the fact that now anaesthesia had altered, and in a very large number of cases gas and oxygen with a basal narcotic were employed. When an ether anaesthetic was employed an enormous amount of secretion was produced, and if atropine were used the type of secretion was so tenacious that it could only be likened to the material round an old scotchine tube which had been long exposed to air. It was impossible to move it save by mechanical means. Personally he had entirely given up atropine in any case in which he had employed gas and oxygen with a basal narcotic, and he had been extremely impressed by the improvement which had taken place in thyroid surgery as a result. Dr. Maxwell was a little out of touch with modern surgery if he thought the surgeon was frightened of his wound bursting. He wanted a deep anaesthesia not for that reason, but because it enabled him to handle the patient gently.

Dr. H. LETHBY TIDY said that he believed there were two factors: first, secretion in the bronchial tree, and, secondly, muscular weakness. Either of these might produce massive collapse of the lung; generally they acted together. The physics of the lung were so difficult that nobody had yet been able to propound a theory which included all the factors. The action of the diaphragm in particular had been neglected.

Professor G. GREY TURNER, from the chair, said that he was one of those who was extremely grateful to the anaesthetists of to-day, but he was still distressed over the calamities which occasionally occurred, such as they had been discussing that evening. He felt that a number of the troubles from which they suffered were due to the half-dead condition of the patients. He thought that pre-medication had gone much too far. In the old days when patients vomited and coughed and were very uncomfortable after operation their ultimate recovery was much more complete. There was certainly a tendency to the abuse of morphine and other sedatives. He thought it also important that patients should be adequately bandaged after operation. It had become the fashion in many clinics to dispense with bandages and to be content with strapping fixed on the dressing, but that made the patient anxious to suppress his desire to cough; he ought to be encouraged to cough, and even aided mechanically to do so. He thought it a pernicious practice for patients—

in intestinal flatulence, did not attach much value to them in gastric flatulence. His own experience suggested to him that, for some reason which he could not explain, they were of use in that condition. He did not agree with Sir Arthur Hurst's praise of charcoal for the relief of flatulence. Dr. T. JENNER HOSKIN pointed out the importance of flatulence in heart trouble. One could say that it was like the trigger in angina pectoris. He had seen many cases in which flatulence had been the cause of acute pulmonary oedema and paroxysmal tachycardia. In fact, he always felt that in the management of heart cases the treatment of flatulence was almost the main consideration. He also stressed the importance of a strict diet. The PRESIDENT spoke of the importance of giving patients who had undergone an abdominal operation a light, easily digested diet. He alluded to one cause of painful flatulence—namely, a troublesome spastic colon.

Professor COHEN, in reply, said that he would not like to claim that prostigmin or acetylcholine, of which he had little experience, or pituitrin, of which he had some experience, was of no value in paralytic ileus, but they must be used with some consideration, and regard must be paid to treatment by fluids and also the administration of chlorides. There was great loss of chlorides in many of these cases of paralytic ileus and they required replacement by rather more than the normal amount of chloride in normal saline. With regard to flatulence accompanying cholecystitis, he thought there were three factors which played a part, if not the whole part, in the flatulence of gall-bladder disease. The first was aerophagy, the second was the muscle tension which accompanied the gas content of the stomach, and the third—a factor commonly overlooked—was an associated chronic hepatitis. He hoped he had not said that gastric carminatives were of no value whatever. What he had said was that they should not be used in simple cases of aerophagy. He thought they had a certain value in some cases of gastric flatulence.

MASSIVE COLLAPSE OF THE LUNG

At a combined meeting of the Sections of Surgery, Medicine, and Anaesthetics of the Royal Society of Medicine on March 2, Professor GREY TURNER presiding, the subject of discussion was massive collapse of the lung as a complication of surgical operations. There was such a large attendance that in the middle of the meeting the audience had to proceed to a bigger hall.

Underlying Factors

Mr. C. PRICE THOMAS said that it was a moot point whether bronchial occlusion was the only cause of atelectasis. It explained perhaps 98 per cent. of the cases, but others were difficult to explain on that ground. Patients were occasionally seen in whom atelectasis occurred suddenly, and this could not be the result of occlusion as there was not sufficient time for the absorption of the contained air. Some hours must ordinarily elapse before atelectasis was produced, and the explanation of a neuromuscular basis would have to be brought in to account for this group of cases. If it was accepted that massive collapse was the result of bronchial occlusion, then a review of the incidence of the condition was timely. The two factors concerned were the presence of secretion and the patient's inability to expel it. The secretion was characteristically thick and tenacious, and its mechanical dislodgment by suction tube needed a fairly strong pump. He did not believe that the type of anaesthesia employed played any great part in the production of the condition. The type of operation was much more important. It was after abdominal operations that most of the cases occurred, and after upper abdominal operations more frequently than after lower, except that appendicectomy with drainage or an operation for appendix abscess also showed a rate of production of massive lung collapse which approxi-

mated to that of the upper abdominal type. Sepsis had been suggested as the cause of this condition, but it was doubtful whether sepsis *per se* had any influence on its genesis; more probably the consequent post-operative rigidity was the chief factor.

Rival Theories

Dr. JAMES MAXWELL said that the impression had been given that there were two schools of thought with regard to the production of massive collapse—one which emphasized diaphragmatic paralysis and the other bronchial occlusion. There was no doubt that bronchial occlusion was the cause of spontaneous massive collapse, but did this mean that the original thesis was necessarily entirely wrong? It seemed to him that these two views could be reconciled, and that a real understanding could then be reached of spontaneous post-operative massive collapse. Why did that block of muco-pus accumulate in certain circumstances? It seemed to him that if a local factor, a weakness of the diaphragm, were postulated, an answer was given to the question why such accumulation was localized in a given area. The two views were not opposed to each other; in his belief there was a great deal in the theory of diaphragmatic weakness causing the localization of a block of muco-pus in the bronchus. He emphasized the great importance of the cough reflex in keeping the respiratory tract clear. In man the cough was a natural means of clearance, and he did not think that some people realized how much damage was being done to the patient if for any reason they discouraged the cough reflex. He knew that the surgeon did not like the patient to cough because it meant that he might burst his stitches, but it might be wiser to put in stronger stitches.

The group of factors responsible for massive collapse were as follows: (1) debility, either local or general; (2) the state of the bronchial passages from the point of view, first, of a tendency to bronchitis, and, secondly, of a tendency to asthma; (3) pre-operative and post-operative medication. On this last point he mentioned that morphine was a very noxious drug in this connexion; it was perhaps the most potent respiratory depressant known. One had only to take a semi-conscious patient and give him a dose of morphine to see the great slowing down of the respiratory movement that followed. The patients who were given generous doses of morphine before and immediately following operation were being placed in exactly those conditions which predisposed to spontaneous post-operative massive collapse.

The Clinical Picture

Dr. Maxwell then turned to the clinical picture. The symptoms were extremely like those of pneumonia. One misleading symptom was acute pain in the chest; it varied with respiration, was worse on inspiration, and simulated exactly the pain of acute pleurisy, but it was not due to acute pleurisy. It was most likely the result of a sudden increase in the negative tension in the pleural space. Dyspnoea was not a very frequent event unless the whole lung was involved. These patients were frequently very ill, and it was always difficult to disentangle that part of their illness which was due to their recent operation from that part which was due to the chest complication. There was often a temperature from the damming-up of a certain amount of infected material distal to the block of muco-pus. The first physical sign of the development of massive collapse of a lobe was a weakening of the breath sounds at the base. The percussion note was impaired, sometimes so much impaired as to suggest fluid. When the mediastinum was displaced at all it was displaced towards the side of the lesion. There were two complications—and it was because of the complications rather than of the condition itself that massive collapse was so important—namely, pulmonary suppuration and the subsequent development of bronchiectasis. It was astonishing how rapidly bronchiectasis could develop. It was not a very

and consisted of a tedious but rather trivial illness confined to a more or less suppurative inguinal adenitis, though this was, in fact, less than half the disease. The primary papulo-herpetiform lesion on the penis appeared three to five days after coitus, and vanished, leaving no trace, in eight days. Some swelling in the groin was noticed by the patient seven to twenty-one days after coitus. No known drug had any effect on the bubo. Rest in bed was the main treatment, aided by the intravenous injection of T.A.B. vaccine. Operation was resorted to in about 15 per cent. of the cases. The male was an inefficient transmitter of the disease; for it to take root in this country infected women, or more of them, would have to be imported. The Frei intradermal test was helpful in diagnosis, especially with a pooled antigen prepared for him by Mr. A. H. Walters from glands in which Dr. Findlay had shown the presence of active virus by animal inoculation. Dr. Hanschell described certain lesions in the rectum of a male patient suffering from proctitis who gave a repeated positive Frei test with the pooled antigen. This was perhaps a direct early infection of the rectal mucosa with the virus, due to sodomy (confessed) while abroad. He concluded by saying that the names "climatic bubo" and "lymphogranuloma inguinale" should be scrapped, and "poradenitis venerea" adopted, as suggested by Dr. Stannus.

Dr. C. C. CHESTERMAN described what he termed poradenomyphilitis as it occurred in male and female native patients at the hospital of the Baptist Missionary Society, Yakusu, near Stanleyville, in the Belgian Congo. He agreed as to the remarkable specificity of Frei's intradermal test, and stated that where that and the Demelcos test for chancreoid were negative strong presumptive evidence of syphilis was afforded in doubtful cases of genital sore accompanied by inguinal bubo. In males the typical puckered groin scar with fistulous openings was often observed, together with involvement of the scrotum. In women, mostly of the prostitute class, four points were stressed. First, the rarity of inguinal adenopathy, which was noticed only in one case in ten when the primary sore was on the fourchette; it subsided without the formation of fistulae. Secondly, the frequent development later on of rectal stricture—in five cases out of six in which the infection had lasted two or more years. In Dr. Chesterman's opinion this was a natural extension of the disease and was not due to rectal coitus, because there seemed no evidence nor motive for this practice in that district, and also, as Dr. Hanschell had pointed out, rectal infection was unlikely on account of the short period of infectivity in the male. Rectal stricture occurred between 5 and 9 cm. from the anal orifice, and was generally accompanied by ulceration, a foul discharge, and the passage of ribbon-shaped blood-stained faeces; not infrequently fistulae were found. A third point was that ano-vaginal fistula was noted in three cases, but all attempts at surgical closure failed. Lastly, the primary lesion, commonly on the labia minora or vestibule, tended to persist as a chronic ulcer; the mucous surfaces involved became indurated with tags and perforations, and the skin-covered tissues became elephantoid.

Experimental Investigation

Dr. G. M. FINDLAY said that as a result of experimental investigation it was now realized that lymphogranuloma inguinale (poradenitis venerea) was a generalized disease, and in addition to such lesions as a primary sore with inguinal bubo, proctitis, stricture of the rectum and vagina, and elephantiasis of the penis, scrotum, or vulva, there had been noted in man conjunctivitis, arthritis, skin rashes, and meningitis. Experimentally the disease could be conveyed to monkeys other than rhesus monkeys, mice, guinea-pigs, cats, and dogs by intracerebral injection, which caused a fatal meningitis. In guinea-pigs and dogs inguinal buboes could be produced by injection into the groin, while injection into the prepuce in monkeys led to inguinal adenitis; the virus could also pass through

the scarified skin. It travelled almost entirely by the lymphatics, and the essential lesion was a reaction of the mesodermal elements in the lymph channels, which become blocked with large mononuclear cells, plasma cells, and lymphocytes with the formation of characteristic nodules in the meninges or meningeal septa of the brain. There was considerable evidence to suggest that the actual virus agents were small granules of the same dimensions as the vaccinia virus. These granules were found in the pus from inguinal buboes, in experimental lesions in animals, and in the chorio-allantoic membrane of the developing chick embryo which had been infected with virus-containing material. The most satisfactory diagnostic method was the isolation of the virus by intracerebral injection of suspected material into monkeys or mice. In addition a number of immunological tests had been employed, of which the best-known was the Frei test, which appeared to depend on the presence of killed elementary bodies in the material injected. It was thus comparable with the allergic reaction following the injection of the killed elementary bodies of vaccinia. Another test, proposed by Wassén, consisted in the injection of a mixture of virus and serum intradermally into guinea-pigs. When the serum contained immune bodies no reaction occurred, but if immune bodies were not present a small papule appeared and broke down to form an ulcer in about forty-eight hours. The intravenous injection of Frei antigen in man was also said to give rise to a febrile reaction if the persons were infected with the virus of lymphogranuloma inguinale, while in normal persons no reaction occurred.

Psychiatric Treatment in Scotland

At a meeting on February 18 of the Edinburgh Women Citizens' Association Dr. David Yellowlees, medical director of the Lansdowne Clinic for Functional Nervous Disorders in Glasgow, said that psychological factors had not been sufficiently allowed for by the law in its treatment of delinquents and criminals. Some people would like to say that mental disease was the one and only cause of delinquency, but the condition was not so simple, for it was too sweeping to assert that no delinquent was mentally normal. It was true to say, however, that no delinquent was as fully developed mentally as he might be. Some delinquents suffered from mental defect, some from a psychoneurotic condition, and a small number from actual insanity. Emotional instability was also a factor. The neurotic group of delinquents suffered not from any inherent defect, intellectual or moral, but from a lack of balance. He thought there would always be need for laws and penalties, although more discrimination was necessary; if a citizen was normal enough to enjoy a citizen's privileges he was normal enough to take a citizen's responsibility.

Dr. G. L. Linklater, school medical officer, Edinburgh, lecturing to the same association on February 22, dealt with exceptional children and their needs. Many children who were called dull, he said, were merely the subjects of mental inertia and took longer to bestir themselves mentally, while many who were regarded as bright, particularly because of verbal fluency, had no depth of intelligence. Too often, however, the apparently dull child who was subject to scorn became self-doubting and soured. The brilliant child was apt to be praised and to develop a self-esteem which was unwarranted, so that he came to be found out, and, with his disillusionment, developed a reaction against society. The prevention of these extremes of estimation lay in testing children for intelligence so that their education could be planned on lines suited to

speaking, of course, of non-emergency operations—to be taken on to the operating table straight off the street, as it were. It was wrong to put off entering the hospital or nursing home until the very last moment, and to expect a considerable operation to be carried out next day. Also—it was perhaps heresy to say so—he could not help going back regretfully to the old days of skilfully given chloroform anaesthesia, for he remembered so well what wonderful recoveries were achieved.

PRURITUS VULVAE

A discussion on pruritus, with special reference to pruritus vulvae, was opened by Dr. R. M. B. MACKENNA and Miss R. NICHOLSON, at a meeting of the Liverpool Medical Institution on February 17, with the president, Dr. E. GILBERT BARK, in the chair.

Dr. MacKenna emphasized the importance of recognizing the condition known as lichenification when dealing with cases of localized pruritus, and summarized the possibilities of treatment by internal remedies, local applications, and psychological methods. Unless an attempt was made to determine the cause of the pruritus in any given case, treatment of the symptom itself was of little avail. Miss Nicholson remarked on the necessity of local examination and of a search for the cause before the treatment of any case of pruritus vulvae was begun. Smegma round the clitoris and nymphae, uncleanliness, pediculi, and threadworms were simple causes and easily dealt with. Vaginal discharges due to endocervicitis might be treated by pessaries, by ionization, and by diathermy of the cervix. The *Trichomonas vaginalis* might also be responsible for pruritus. Abnormal conditions of the urine, including glycosuria, hyperacidity, and oxaluria, were mentioned, and the escape of urine in cases of prolapse or vesico-vaginal fistula, and in later years even poor sphincter control alone causing leakage of a few drops of urine after micturition. Careful drying and sponging after micturition was recommended. Irritation during pregnancy was relieved by alkaline baths and calcium internally. The view of Swift of Australia was that achlorhydria, causing a lack of absorption of vitamin A, was an aetiological factor in this condition, and he advised treatment by the oral administration of dilute hydrochloric acid and vitamin A.

In the discussion which followed Dr. ISABELLA BUTLER spoke on the treatment by electrical methods of pruritus associated with leucorrhoea due to a chronic cervicitis. Diathermy or ionization of the cervix, high-frequency treatment, small doses of x rays to the vulva, and ultra-short-wave therapy using Schliephake's vaginal electrode were possible methods of treatment. Mr. PERCY MALPAS said that the greatest problem in practice was the treatment of those cases of pruritus vulvae for which no local cause could be found. *Trichomonas* infection should be suspected even if there was little or no vaginal discharge, and especially when the symptoms caused by leucorrhoea were out of all proportion to the apparent severity of the discharge. A useful practice was to restrict the amount of sugar in the diet; many patients exhibited a transient glycosuria, usually due to excessive tea-drinking, which might not always be detected at the time of examination. Injections of A.B.A. were not as successful in the treatment of pruritus vulvae as in pruritus ani. As a local dressing the use of drying powders such as talcum might have received more attention. Sympathectomy was inadvisable, but good results had been seen in very severe cases after division of the pudic nerves in Alcock's canal, the only disadvantage of this procedure being the resultant anaesthesia.

Mr. T. N. A. JEFFCOATE said that the administration of oestrogenic hormones was called for only when there was evidence that the pruritus was caused by an atrophic condition of the vulva and vagina; large doses, preferably of the benzoate preparations, were usually required and the results were excellent. Oestrogenic compounds

rarely helped those patients in whom there was no evidence of an underlying ovarian deficiency. Local division of sensory nerves was a useful means of dealing with intractable pruritus of unknown origin. Dr. R. W. BROOKFIELD commented on the influence of vasoconstrictor drugs on generalized pruritus. Ephedrine and adrenaline frequently afforded relief in the itching of urticaria, and he had found that the intolerable pruritus associated with the severer forms of serum sickness, though it might not respond to adrenaline, was relieved in dramatic fashion by the injection of pituitrin. The same result had been observed in the itching of chronic jaundice.

Cardiac Failure

At the same meeting Dr. G. RONALD ELLIS read a short paper on cardiac failure.

Dr. Ellis said that the fundamental problem in cardiovascular pathology was concerned with the immediate cause of the majority of cases of heart failure. Why did the patient with old-standing symptomless aortic regurgitation suddenly develop symptoms of heart failure, when it was known that the valvular lesion had undergone no change for many years? After discussing those instances, as in massive infarction, in which the anatomical findings did seem adequately to explain the cardiac insufficiency, Dr. Ellis described the microscopical changes in the myocardium, and pointed out that for the most part they did not explain the sudden failure. The explanation was probably to be sought in some metabolic change in the heart muscle akin to fatigue in skeletal muscle. In the young person with pneumonia whose heart was healthy primary failure probably never occurred; the circulatory failure being peripheral in type, and symptomatic really of "shock."

In the discussion which followed Professor JOHN HAY referred to the causes of failure in hearts already affected by prolonged strain. The precipitating factor was usually the onset of auricular fibrillation, some toxic process such as influenza, or a defective supply of oxygen to the myocardium, caused by anaemia or a narrowing of the orifice of a coronary artery. Coronary occlusion in late middle life was another factor which had to be borne in mind. Dr. A. J. MCCALL said that myocardial damage due to syphilis was usually attributed to occlusion of the coronary orifices by syphilitic aortitis. A diffuse gummatous infiltration of the myocardium was sometimes found; and, as emphasized by Warthin, might be more common than was generally supposed. Jaundice appearing suddenly in a patient with congestive cardiac failure was frequently attributable to pulmonary infarction. A case of myxoedema with severe angina pectoris was described; both conditions responded to thyroid therapy.

PORADENITIS VENEREA

At a meeting of the Royal Society of Tropical Medicine and Hygiene at Manson House on February 17, with the president, Lieutenant-Colonel S. P. JAMES, in the chair, a discussion on "climatic bubo or lymphogranuloma inguinale" was opened by Dr. H. M. HANSCHALL.

Dr. Hanschall reviewed the 130 cases, all male, seen at the Royal Albert Dock Hospital during the last eighteen years. He expressed his indebtedness to Dr. Marshall Findlay, who had carried out animal inoculations for him, and to Dr. H. S. Stannus, "whose scholarly researches had opened a window on the full extent of this infection." The cases had been studied against a background of nearly 18,000 men with lesions of the genital and inguinal areas, including gonorrhoea, attending the venereal diseases clinic in the same period. All the cases had been infected in the Tropics or sub-Tropics; in eighteen years he had detected no case infected in this country. The condition was strictly a venereal disease of the male and of the Tropics;

reference. Among them was a great-great-grandson of Lennons, Mr. Hugh Elliot. Mr. H. L. Eason replied in a characteristically humorous speech, in which he referred to the "inferiority of Guy's men in the presence of men from Bart's." Mr. Elliot in a few remarks recalled the description his grandfather had given him of Lettison's funeral.

District Nursing in London

The annual meeting of the Central Council for District Nursing in London was held at the County Hall on February 24 with Sir William J. Collins in the chair. The twenty-third annual report, which was adopted, stated that the council had again received from the trustees of the London parochial charities a grant of £4,000, which sum, together with £400 from the funds of the council, had been distributed to seventy-four district nursing associations in affiliation. During the year the council had also distributed £7,575 contributed by the London County Council in aid of the public assistance work performed by district nursing associations. It was mentioned that the home nursing of persons coming within the scope of public assistance had continued smoothly. The cases visited for general nursing and for administering insulin to diabetic patients had numbered between 1,200 and 1,400 each quarter, and the number of visits each quarter about 50,000. The visits for insulin administration were paid for by the L.C.C. at the fixed rate of 6d per visit. The grant for general nursing worked out at between 9^d and 11^d per visit. The central council during the year awarded six bursaries to enable district nurses to take courses in midwifery and maternity work, and fourteen bursaries to enable nurses practising midwifery to study the administration of analgesics. A recommendation was proposed to the meeting from the executive committee, and agreed to, that in view of the increased cost of district nursing and of the inadequacy of the present grants from local authorities it is desirable that payments by borough councils for nursing services under statutory powers be made upon the basis of a consolidated subscription rather than upon a per visit basis. The constituent nursing associations are being asked to take up this question with their respective borough councils. It was stated that the London County Council had already had some discussion with the borough councils in regard to the nursing of maternity complications and the possibility of payment by the borough councils by block grants based on statistics for the past three years. The executive committee was re-elected, one new medical member being added in the person of Dr. P. B. Spurgin, who was proposed by Dr. W. Paterson and seconded by Sir Comyns Berkeley, and the finance committee, with Sir Stanley Woodward as the medical member, was also reappointed.

Guy's Hospital Dental School

Guy's Hospital Dental School celebrated its forty-ninth anniversary on March 5 by an annual clinical meeting, and between 400 and 500 past students returned to renew old acquaintance and to witness demonstrations of modern procedures by members of the present staff. The school presented a busy and crowded appearance throughout the day. Operations of dental interest proceeded in the two theatres, demonstrations of anaesthesia in the general anaesthetic room, pathological specimens were shown in the dental research laboratory, and clinical cases in the conservation department. In the children's department orthodontic cases were shown, prosthetic cases in the denture room, and an exhibition of students' work in the prosthetic laboratory. At a luncheon presided over by the dean of the dental school (Mr. T. J. Evans) it was mentioned that Guy's is the largest dental school of the Empire, and provides the Empire with one-fourth or one-fifth of its dental practitioners. The number of students, which has to bear a certain proportion to the number of medical students, is about 360. The various sections now contain 114 dental chairs, the attendance of patients

in the year has risen to about 100,000, and last year the work done for patients comprised 27,000 fillings, 25,000 extractions, and 2,200 dentures. In the children's department over 1,200 children were under treatment during the year for regulation of teeth and correction of facial deformities, and in the x-ray department over 7,000 patients were dealt with. Emphasis was laid on the need for more room, a difficult problem at Guy's in view of its situation in a crowded London area, but it is hoped that the jubilee next year may be marked by some extension. It was in February, 1889, that the first dental student entered Guy's. The first dental school consisted of a single room with twelve wooden chairs. But the interest of Guy's in dental education dates back much earlier: a dental surgeon was appointed to the staff in 1799. The dean pointed out the understaffing of the dental profession: there are only three dentists for every 10,000 of the population, and dentistry is almost the only learned profession which still provides any amount of room for young people.

Analytical Chemists' Dinner

The Society of Public Analysts and Other Analytical Chemists held a dinner on March 4 to commemorate the sixty-fourth anniversary of the foundation of the society. In proposing the toast "His Majesty's Judges" Mr. E. R. Bolton said that they were the admiration of the world. He made a plea for the institution of a Chair of Chemical Jurisprudence. In response Mr. Justice Singleton paid a tribute to the courage and right-doing of juries who had to determine important questions of fact. The efficiency of juries and the interest and trouble taken by jurors, both men and women, in a serious case to get the right result spoke well for the future of this country. In proposing the health of the society Mr. Norman Birkett, K.C., said that while he agreed with Mr. Bolton in his eulogy of the judicial bench, there were times when he felt that the jury had not taken a correct view of the case. In reply the president, Dr. G. Roche Lynch, asked these present to drink the health of Dr. Bernard Dyer, the only living foundation member of the society. Mr. A. L. Bacharach proposed the toast of "The Guests," and Lord Cornwallis, Sir Philip Game, and Sir Robert Pickard replied.

Committee Against Malnutrition

At a meeting held by the Committee Against Malnutrition at the Royal Society of Arts on March 3 to emphasize the nutritional aspects of the national fitness movement, Miss Marjorie Green (secretary of the Children's Minimum Council) recalled the grave doubts that had recently been expressed regarding the "assessments of nutritional states" in the schools. Quoting from the findings of Mr. Huws Jones in Liverpool and from private communications received from a number of school medical officers, she considered that part of the difficulty lay in the interpretation of the term "normal." Was this a standard of full physiological attainment or merely an average? Experience suggested that we had come to accept one standard for children of the well-to-do and another for children of the poor. The present methods of assessing malnutrition in school children were valueless from a scientific point of view, and from a practical point of view were certainly dangerous. Professor W. E. Le Gros Clark thought that in any scheme to improve national health and physique it was essential to have data regarding the present standard of the population, and particularly of the growing population. It was not easy to find a standard of normality, though this was essential. Rejecting the height-weight-age index as insufficient, the speaker mentioned with approval the ACH index employed by the American Child Health Association; work of this description needed the co-operation of statisticians, anthropometricians, and, above all, of expert clinicians accustomed to the examination of children. Professor Le Gros Clark referred to experiments that were in

capacity and speed. Under-nourishment was an important factor, which, however, was less prevalent among school children to-day than ever before; the pre-school child, however, had not improved in this respect as he ought to have done. The city of Edinburgh proposed to build a unit in country surroundings where there would be provision for a limited number of children who might be termed pre-delinquents or children who under the observation of the teaching staff showed "difficult" tendencies. These children required a change of environment, detailed observation, and treatment. Children who were subject to fear had frequently been too much shielded and had not developed the courage and experience necessary to face the world; they needed to be encouraged to mix on terms of equality with their fellows.

Central Midwives Board

At a meeting of the Central Midwives Board for Scotland Professor R. W. Johnstone and Professor James Hendry were elected chairman and deputy chairman respectively for the ensuing year. The Board appointed examiners and approved, subject to inspection, the list of recognized training institutions, with their teachers, for the training of pupil midwives.

Professor of Dentistry at St. Andrews

A chair of dentistry at St. Andrews University was recently established by a gift of £17,500 from Mr. William Boyd of Dundee, who is chairman of Dundee Dental Hospital, and the University Court has appointed Dr. H. Gordon Campbell, dental surgeon of Dundee, to be the first occupant. Dr. Campbell, who qualified in medicine L.R.C.P. and L.R.C.S., Edinburgh, in 1904, has been lecturer on dental anatomy in the Dundee Dental School and dental officer to the Dundee School Board since 1913. He has done a considerable amount of organizing work in connexion with dental surgery, having been secretary of the Dundee Military Dental Service, which was the first of its kind in the country at the outbreak of the war. He also organized the Dundee Dental Health Association, through which Dundee dental surgeons have given addresses to the public on the importance of the care of the teeth and mouth.

Inquiry into Physical Welfare

It was stated at the annual meeting at Dunfermline on March 4 of the Carnegie United Kingdom Trust that the trustees had set aside a sum of £10,000 to meet the cost of an inquiry into the connexion between the economic and social factors influencing physical welfare. The inquiry will be under the direction of Sir John Orr of the Rowett Research Institute, Aberdeen. It was also stated that in the allocation for 1936-40 a sum of £150,000 had been set aside for land settlement development and that up to the end of last year £68,000 had been paid in grants to the land settlement association. The general purpose of this association is to test the possibility of creating a new opportunity of earning a healthy, happy, and prosperous livelihood by cultivation of the soil and breeding of stock for men in the special areas whose chance of employment has ceased. This association now controls twenty-five estates, comprising 11,000 acres and providing for the establishment on small holdings of about 7,000 persons from the special areas.

District Nursing

The annual report of the Scottish Council of the Queen's Institute of District Nursing for 1937 shows that in the previous year out of the registered births in Scotland numbering 88,928 Queen's nurses attended 14,612, or approximately one-sixth of the whole number. Of these, 2,467 cases were attended by the nurses acting as midwives, and the remaining 12,145 cases by nurses acting under the direction of a medical practitioner. The maternal mortality among cases attended by the Queen's nurses was 3.6 per 1,000 births, while in the other cases

in Scotland the rate was 5.9 per 1,000 births. In view of the increase in salaries of Queen's nurses in England the Scottish Council also decided to make an increase, the nurses in Scotland being put from January 1 last on a scale commencing at £75 rising to £100 per annum for those undertaking maternity nursing, in addition to allowances for board and uniform.

ENGLAND AND WALES

Welsh Board of Health: New Headquarters

On March 1 the Minister of Health, Sir Kingsley Wood, opened the new headquarters of the Welsh Board of Health in Cathays Park, Cardiff. He recalled that the department had its origin in the National Insurance Act, 1911, which was conceived in the fertile mind of one of the greatest of all Welshmen, Mr. Lloyd George. Under the Welsh Board of Health 900,000 working-class people in Wales received medical attention and treatment, 1,000,000 people contributed to the pensions scheme, and 200,000 now received pension allowances. The building would be devoted to war against disease and ill-health, particularly in the interests of two great causes—care of the mother and child and welfare of the blind. Mr. Arthur Greenwood, M.P., a former Minister of Health, said he hoped the building would not only be the latest embodiment of the Welsh spirit of nationality but would become a power-house radiating its influence into the homes of the humble folk in Wales.

Medical Society of London

The Medical Society of London held its 163rd anniversary dinner on March 1, with the president, Mr. J. E. H. Roberts, in the chair. After the loyal toasts had been honoured the health of the Society was proposed by Mr. R. H. Bernays, Parliamentary Secretary to the Ministry of Health, who began by saying: "We politicians have to face up to our results; you can put your results underground." The Medical Society of London, he continued, was the oldest in the country and had helped to advance knowledge in both medicine and surgery. It had also played an important part in preventive medicine, "which means 'Consult your doctor, and consult him in time.'" Lettsom, the founder of the Society, had interested himself in such matters as ventilation and dietetics, and in 1798 had published a tract entitled "Hints respecting the Effects of Hard Drinking." Among other past presidents of the Society Mr. Bernays referred to Dr. John Snow, who had removed the Broad Street pump handle in the cholera outbreak, and to Sir Benjamin Ward Richardson, who had coined the phrase, "National health is national wealth"—which every Minister of Health had since produced as a brilliant impromptu. Mr. Bernays ended a witty speech by making a plea for co-operation between the voluntary and municipal medical services. In responding, Mr. Roberts said that the finances of the Society were on a satisfactory footing, that its meetings had never been better attended, and that the number of Fellows was higher than it ever had been. The Society had recently been presented by Colonel Clutterbuck with a Fothergillian medal and a set of bleeding instruments which had belonged to his forebear, Dr. Henry Clutterbuck, who was president of the Society in 1819. In the early days the Society used to meet in private houses and taverns in the city, until in 1788 it acquired a house of its own. In 1850 the Society moved to George Street, Hanover Square, and in 1871 they acquired the lease of their present house in Chandos Street, which was now, however, no longer modern and too small for their needs. In four years' time certain leases would fall and the question of a building for the Society would then become urgent. The health of the guests was proposed by Mr. Alex. E. Roche, who welcomed each guest in turn with a short and apt biographical

accepting the responsibility in suitable cases of treating malignant disease if a cure is to be achieved by surgery or by radiotherapy. The condemnation of irradiation as a method because of rare cases of overdosage and damage is as groundless as the disparagement—in London, too, and towards the end of a dark winter—of the virtues of ultra-violet light!—I am, etc.,

London, W.1, March 5.

J. H. DOUGLAS WEBSTER.

SIR.—Mr. Percy Furnivall's account (February 26, p. 450) of his treatment by radium and x rays for a small epithelioma indicates what must have been suffered by many patients following similar treatment. His trigeminal pain was almost certainly due to the radio-necrotic ulcer remaining at the site of the primary lesion. Perhaps surgical excision by the knife or by diathermy would leave an ulcer with a normal blood supply which would granulate normally, besides providing immediate relief of the pain and a corresponding improvement in the patient's condition. The reason for the radio-necrosis is, without doubt, local overdosage. I think there is good evidence to show that such overdosage can be avoided to a large extent by ensuring that the radium or radon is distributed in such a way as to ensure homogeneous tissue dosage totalling 5,500 to 6,000 r over about two weeks. The physical principles and their clinical application in the treatment of lesions by radium have been worked out by various investigators. In England, Mayncord of the Cancer Hospital and Paterson and Parker of the Holt Radium Institute, Manchester, have provided us with adequate data, and the papers of the latter workers are particularly useful. I hope that the experience of Mr. Furnivall will persuade more of the people engaged in radium therapy to apply the principles of radium dosage rationally. With regard to the treatment which he received in America, I feel sure that the principles above described were not followed, because in a recent visit to America I found no clinic in the United States, of many visited, where accurate spacing and application of these principles were carried out. The malaise and local symptoms due to the x rays were unavoidable, and with such a dose only temporary. I think that the account given by Mr. Furnivall justifies a special plea for extreme care and the rational scientific application of known principles in dealing with every case treated by radium or radon. Mistakes are bound to occur in everyone's experience, but will be much less common if this plea is heeded, while the reasons for them will be understood.—I am, etc.,

F. ELLIS,

Sheffield, March 2.

Medical Director, Sheffield Radium
Centre, Royal Infirmary.

SIR.—I am surprised at the number of letters I have received from strangers about radium treatment, following the publication of my own case in Clinical Memoranda on February 26. I hope to answer them all in time. These letters show that disastrous results occur more frequently than I had any idea of; and that patients are not told beforehand of the possibility of such results. I am now more than ever convinced of the necessity of further research on the effects of radium emanations, and care in selecting cases for radium treatment; also the inadvisability of handing out radium for indiscriminate treatment.—I am, etc.,

PERCY FURNIVALL,
Consulting Surgeon to the
London Hospital.

Northam, N. Devon, March 5.

Scapulo-humeral Periarthritis

SIR.—I have read Dr. Douthwaite's article in the *Journal* of February 26 with some interest, more particularly as I disagree largely with the views therein expressed.

I have treated a number of cases of periarthritic fibrositis of the shoulder-joint by the method advocated by Dr. Douthwaite, but have long given it up in favour of less drastic but equally satisfactory methods. Though it may prove quite a satisfactory proceeding to break down by forcible measures isolated adhesions resulting from injury to an otherwise healthy shoulder, it is quite another matter when the joint capsule, subacromial bursa, tendons, and other structures are all matted together by diffuse periarthritic fibrositis. The force required to break down adhesions in such cases and obtain immediate free movements of the joint is very considerable, and inevitably results in injury of the tissues involved. I personally know of one case where an enthusiastic manipulator succeeded in causing a fracture through the neck of the humerus, and I understand that this is not an isolated instance. Forcible tearing of adhesions results not only in "loud snaps" but in exudation of serum or blood, with inflammatory reaction likely to set up more fibrosis and so retard, rather than hasten, the patient's ultimate recovery. The majority of these patients, as Dr. Douthwaite's cases show, are middle-aged or elderly people, many of them in indifferent health, and it appears quite unnecessary and, I venture to think, quite unjustifiable to subject such patients to the severe general disturbance and still more severe pain which may last for a week or more after forcible tearing of adhesions.

Dr. Douthwaite's observation that the treatment of this condition by baths is "futile and waste of time" argues a lack of experience. These cases, which incidentally are very common, respond, as a matter of fact, quite well to suitable forms of balneological treatment such as hot "undercurrent" douches in an immersion bath, hot packs, manipulation in a pool bath, etc., followed by massage and graduated passive movements. Treatment should, in any case, be sedative in type with a view to relaxing muscular spasm—to which, incidentally, much of the pain and rigidity is due—increasing circulation through the neighbourhood of the joint, and reducing inflammation.

Whatever form of treatment is adopted it is quite true, as Dr. Douthwaite remarks, that the active co-operation of the patient is required to attain a satisfactory result. My own experience is that as this "active co-operation" is so much more painful following forcible manipulation than it is during or after a course of balneological treatment, one is more likely to obtain it with the latter. Having given both methods a fair trial, I can confidently say that treatment on the lines I have indicated above is equally satisfactory and much less painful, and so less detrimental to the general health of the patient, than that advocated by Dr. Douthwaite.—I am, etc.,

Bath, March 1.

F. G. THOMSON, M.D., F.R.C.P.

SIR.—Under this title Dr. A. H. Douthwaite has described (*Journal*, February 26, p. 441) a condition which has attracted attention during the last few years. Possibly this has been so, not only because of the number of sufferers but because of the success of treatment by movement of the joint under anaesthesia. In the majority of cases treatment by heat, massage, and exercises alone seldom cures the condition. Dr. Douthwaite has cured

progress to determine whether the rate of growth of the finger-nails could be used as an indication of the nutrition of children, and remarked on the value of the vitamin tests now employed by Dr. L. J. Harris. In his own opinion it would be necessary to discover the "normal" from an examination of a large sample of children known to come from families which were comfortably off and to have had the benefit of a good diet and wholesome environment. Professor J. R. Marrack, illustrating his remarks with slides, gave a brief account of the development of modern dietetic knowledge. He referred especially to the effects of deficiency of vitamin A upon the visual purple and upon the surface of the eye; it was probable that such deficiencies manifested themselves in slow rate of growth and in impairment of the powers of the epithelium to resist infection. It was, in the speaker's opinion, undesirable to rely on vitamin doses; the necessary constituents should be obtained from a thoroughly balanced diet consumed in comfort and without anxiety of mind. Only then could the body take full advantage of the food absorbed. Dr. Janet M. Vaughan also illustrated her remarks with slides, showing statistical evidence of anaemia in the women and infants of the working class. It was her task to explain the character of one type of food deficiency as it affected the health of the population. While iron preparations could effect surprising improvements in health, it was better that the iron should be supplied through the normal diet. Women had informed her that the iron medicaments had the disadvantage of "making them feel too hungry." This in itself suggested that an all-round supplement of diets in poorer families was necessary.

Correspondence

After-effects of Modern Treatment of Carcinoma

SIR,—It would be a thousand pities were Mr. Percy Furnivall's account (*Journal*, February 26, p. 450) of his unhappy experience following radiation treatment for an epithelioma of the pharynx to receive wide acceptance as an accurate picture of what is to be expected as the normal or usual sequence of events.

The position that Mr. Furnivall made for himself in the surgical world a decade ago, and his reputation for cautious judgment and keen inquiry, coupled with very natural sympathy for his protracted sufferings, will naturally focus the attention of all who are in any doubt about the best method of dealing with this kind of growth, and may put a brake on the onward march of progress which in this type of carcinoma in particular has shown such notable advances.

These advances have not been gained without many misadventures, but happily they are becoming increasingly rare; and if there is one fact that stands out above all others in the welter of failures, recurrences, radio-necroses, and all the other miseries that we have had to deal with in the past it is that we have learnt that no matter how carefully and how scientifically radium needles or radon seeds may be implanted, particularly in a soft and yielding structure like the pharynx subject to constant movement and disturbance, it is a physical impossibility to ensure a strictly homogeneous field of irradiation. There are bound to be areas where the degree of radiation is much above the general average of the irradiated field, and if on the top of this a major dose of x rays reaches the affected tissues disaster is only too probable, with the long-drawn-out misery of radio-necrosis as a consequence.

The radium bomb would now appear to be the answer to pharyngeal carcinoma, and is receiving increasing recognition in this country. It is not, of course, a complete answer in every case—that would be too much to hope—but given the necessary care and knowledge on the part of those responsible for its application, and the courage and determination required by the patient to undergo a tedious and distressing treatment, the results are more satisfactory than anything ever seen before, and twelve weeks rather than twelve months may be regarded as the average and normal period of disability.

Mr. Furnivall is a man of high courage, and is, I am sure, not asking for sympathy, but it may be some comfort to him to know that those of us who have had large experience of these cases, and of the kind of complication he has experienced, recognize that in cases where radio-necrosis has been extensive the destruction of the growth is so much the more complete and permanent. His ultimate and complete recovery is therefore assured, and it will be the earnest hope of all of us that it may be soon.—I am, etc.,

London, W.1, March 1.

CECIL ROWNTREE.

SIR,—Mr. James Phillips's remarks on deep x-ray and radium beam therapy (*Journal*, March 5, p. 538) are on a par with his statement that "ultra-violet rays produce senile changes." Can it be thought that the multitudes who travel every winter to Central Europe, the Riviera, and further south in search of the sun find the effect is senility? On the contrary, with few exceptions they return rejuvenated. Individual patients have a "dose limit" for x rays, radium, and sunlight, as they have for certain drugs; the history and clinical judgment should enable one to select cases suitable for full doses in an attempt to cure and cases suitable for milder palliative methods. I can recall patients treated with full courses of deep x rays many years ago for testicular and uterine primary malignant conditions who have not only not suffered but on the contrary are fit for their usual duties and are happy; at my weekly out-patients' follow-up department I see many cases in a state of normal health and good spirits. Not only the total dosage but the time factors in its administration and the methods used (for example, minimal dosage to normal parts) are of consequence, as are associated factors, such as the blood count, diet, exercise, etc.

Mr. Percy Furnivall has been unfortunate in having much pain following the implantation of radon seeds and deep x-ray therapy. In planning such combined treatments it is very difficult to judge the safety margin of total dosage; the intense caustic effect around radon seeds is apt to be followed by pain, still more so if the treatment is supplemented by full doses of deep x rays; hence the increased use in recent years of either deep x rays or tele-radium, without insertion of needles or seeds, for primary malignancy of the tongue and tonsil. Needles or seeds are reserved by many for small, highly resistant residues, or for late recurrences seen at an early stage.

Mr. Phillips seems to regard Mr. Furnivall's disability as due entirely to x rays, whereas it would seem primarily to be an unfortunate result of the insertion of radon seeds, as the local condition is now apparently a radium necrosis: "an ulcer with a wash-leather slough on it about the size of a penny piece where the original growth had been." Mr. Furnivall himself refers to his "radium neuritis and myalgia." "Not too much of anything" is a motto which must often be generously interpreted in

never hope to get another job if she loses her present one, and therefore becomes a time-server to hospital committees, which in many instances are still only too ready to economize at the expense of their nursing staff both in respect of numbers in relation to occupied beds and also as regards the way in which they are fed and housed. I think too that the General Nursing Council and or the College of Nursing should take to themselves greater powers, and pay at least half-yearly visits to recognized teaching hospitals to see that probationer nurses are properly cared for and not overworked.

I hope, Sir, that you will publish this letter and that it may serve to stimulate medical members of hospital committees to inquire more carefully into the conditions under which their nurses work.—I am, etc.,

Great Yarmouth, March 5.

R. LEONARD LEY.

Medical Secrecy and the Matrimonial Causes Act

SIR.—The first cases under the new Matrimonial Causes Act will shortly come before the Courts, and medical practitioners being to some extent affected by the provisions of the Act, it is interesting to examine the position. Evidence from medical practitioners will be required under Sections 2 (d) and 7 of this Act. Section 2 (d) provides that "a petition for divorce may be presented to the High Court . . . on the ground that the respondent is incurably of unsound mind, and has been continuously under care and treatment for a period of at least five years immediately preceding the presentation of the petition." As to whether a practitioner can say that any given person is "incurably of unsound mind" is of course for him to judge.

The real question affecting medical practitioners under this section of the Act is, Does the usual relationship of doctor and patient exist in such cases? It may be said that the patient does not voluntarily come to the doctor under whose care he or she will be, whether in a private or public institution. A patient is placed under the doctor's care by some person or authority who is responsible for the patient—whether it be a relation or a local authority matters little. It may be argued that the doctor is responsible not to the patient but to the person who employs him for the purpose of caring for the patient. In ordinary circumstances presumably a doctor without hesitation would give information regarding the health and prognosis of a patient to a husband or wife. Is, therefore, the extent of the information sought, or the purpose, a factor to be considered by a practitioner in giving or withholding information? It must be remembered that under the Act the interests of the patient in the event of a petition for divorce are safeguarded either by the patient's Receiver or the Official Solicitor, and the financial provisions of the old Act are made applicable to the new Act. Will the doctor, by giving such information, be committing a breach of professional secrecy? By refusing, he will be stultifying the law, particularly so far as poor persons are concerned, for the poor person will not be able to afford to requisition the services of a practitioner from outside the institution to examine the patient with a view to certifying, although those in more fortunate circumstances may be able to do so. Even in the latter case the outside practitioner could hardly form an opinion without being granted access to the records of the patient. It has been suggested that those practitioners working at municipal mental hospitals may seek to cover themselves by getting their visiting committees to direct them to give such

information. Even if it were desirable that practitioners should shelter from their responsibilities in this way, would it safeguard a practitioner from a charge of breach of patient's privilege?

Section 7 is easier. Under it, suits for nullity may be brought on the grounds that either party was at the time of the marriage of unsound mind or a mental defect within the meaning of the Mental Deficiency Acts, 1913 to 1927, or subject to recurrent fits of insanity or epilepsy, or at the time of the marriage suffering from venereal disease in a communicable form, or at the time of the marriage pregnant by some person other than the petitioner. Obviously, here a practitioner must not give information obtained as a result of professional attendance except with the consent of his patient or under the direction of a judge.

It may be said that it is not the business of the medical practitioner to obstruct the law; but before they facilitate the law practitioners are entitled to know that their own interests are not jeopardized. The questions above referred to are of considerable importance as they raise new problems on the much-discussed question of professional secrecy, and the opinions of your readers will be both interesting and valuable to those who are called upon to advise on these questions.—I am, etc.,

RICHARD W. DURAND,

Secretary, London and Counties Medical Protection Society, Ltd.

London, W.C.2, March 7.

The Population Question

SIR.—Dr. Grace Leybourne in the *Sociological Review*, 1934, estimated that there would be a drop between 1931 and 1951 of about four million children (from nine and a half millions to five and a half millions), of workers under 45 of about one million, and an increase of those persons above the age of 45 of about two and a half millions. This is because we have been doing everything to save and prolong life and nothing to encourage its reproduction. Suppose the drop in young and the increase in old people were not so large, even only half that estimated, it would cause a profound economic disturbance in the next fifteen years—think of the schools, training colleges, children's hospitals, the supply of girls as servants and factory hands, of errand boys, typists, and clerks, of miners and labourers, of soldiers, sailors, and air pilots. The Minister of Labour has warned us that there will be a shortage of youthful labour, and the Minister of Health that there will be vacant places in the schools. Who is to pay for the pensions of the increasing number of aged if the earnings of youth fall away?

All the democratic countries, except Canada and Eire, have a birth rate considerably below maintenance level; England, France, Austria, Sweden, Norway, one of 15 per 1,000 or less; U.S.A., Australia, and New Zealand, 17 per 1,000 or less. On the other hand, the birth rate in Italy is 22 per 1,000—fully maintenance level; Germany recently has raised her level from 14.7 to 19 per 1,000. Poland, Yugoslavia, and Rumania have birth rates still considerably above maintenance level: Turkey has added two and a half millions to her population in recent years; Japan, numbering seventy millions, increases by about a million a year. Russia's population is expected to increase from a hundred and fifty to two hundred and fifty millions in twenty years. India under our rule has put on some forty millions in ten years, and now has a population of four hundred millions. It is surely obvious that we cannot maintain the British Empire on a population falling

all his patients, except for two who have had some persistence of pain, and in resistant cases he carries out manipulation at more than one sitting.

The method of manipulation he describes is that "the scapula should be immobilized so far as possible by a band passing around the chest and held on the opposite side by the assistant. Forced shoulder movements must be brisk, and should be carried out in the normal planes of movement." Presumably there was no intention of giving a detailed description of the necessary manipulation of the joint, but the above two statements are obviously open to criticism. Fixation of the scapula by a band held by an assistant has always seemed to me impossible. Movement can be restricted almost entirely if the patient is placed on his face and the scapula held by an assistant, but as this is an uncomfortable position for the operator it is not recommended. Secondly, with regard to movement, it is not clear from Dr. Douthwaite's account if the manipulation should consist in the movements of flexion, extension, abduction, and adduction in the scapular plane only (Johnston, *Brit. J. Surg.*, 1937, 25, 252), or whether rotation is to be acquired by movement in the four directions mentioned.

In manipulating the shoulder the difficulty of fixation of the scapula and manipulation of the humerus on it can be overcome by reversing the procedure. The patient lies flat on his back with the affected side at the edge of the couch. The arm (and scapula) are abducted as fully as possible, the humerus is fixed by grasping the arm with one hand, and the axillary border of the scapula is pushed away from it by the operator's other hand with "brisk movements." This frees abduction. The patient's arm is then internally rotated while still in abduction and the scapula again moved. The arm is then externally rotated and again the scapula is moved. It is most important that the humerus should not be forcibly rotated on the glenoid, as complications, such as effusion into the joint or fracture of the neck of the humerus, are liable to occur in elderly patients.—I am, etc.,

ST. J. D. BUXTON.

Transport of Iron

SIR,—Reading the leading article with the above title on page 455 of your issue of February 26, I was a little disappointed to find no reference to the work of Dr. George Barkan, who has been experimenting and publishing papers relating to the subject for the last thirteen years, and who, in his last communication, in conjunction with Dr. Otto Schales,¹ was, I thought, particularly suggestive and inspiring. The issue of this paper was subsequent to the publication of the book and the two papers mentioned in your article, but it appeared in the early part of the current winter session.

One cannot cover the contents of such a paper in a short letter, but the following points are of interest in the matter of the "leicht abspalgbares Bluteisen," which one may dub the "loose iron" in the blood. The smaller and quantitatively more variable plasma fraction (originally called E¹, and now considered as a pseudo-methaemoglobin), since it appears derived from the larger corpuscular fraction (originally called E, and now considered as a pseudo-haemoglobin), I shall leave over just now, simply stating that the iron in it is supposed finally mostly to leave the corpuscle to become attached to the globulin of the plasma, thereby contributing to the sum of the iron in the plasma. Within the corpuscle oxidative rupture,

at one methine bonding of the porphyrin ring of haemoglobin, is supposed to lead to formation of a pseudo-haemoglobin, from which the iron becomes capable of extraction by weak acid (0.1 N). The deferrification of fraction E fails to yield a porphyrin. The opened porphyrin ring is supposed to yield bilirubin, and to contribute, after combination with serum albumin, to the plasma stock of that substance. The well-known reversible combination of the corpuscular substance yielding "loose iron" with both oxygen and carbon monoxide (the CO affinity said to be 800 to 2,000 times the O₂ affinity) is taken as related to the pseudo-haemoglobin structure, as also the paralysis of the weak acid extraction effect by carbon monoxide.

Barkan's present view, then, is that the substances yielding "loose iron" to weak acid are intermediates in the degradation of some of the haemoglobin of the corpuscle to bilirubin, and, on this idea, a constant slow passage of both iron and bilirubin into the plasma is occurring. The experiments detailed in the paper appear to me to withstand criticism, and I hope that the ideation may assist progress in knowledge of this matter.—I am, etc.,

Edinburgh, March 1.

E. W. REID.

Iron for Subnutrition

SIR,—I was interested in the article on the effect of iron administration in cases of subnutrition, by Drs. E. Blackstock and J. M. Ritchie of Birkenhead, which appeared in the *Journal* of March 5 (p. 512).

For at least ten years at the Heckmondwike School Clinic I have recommended ferri et ammon. cit. to parents whose children presented a clinical picture similar to that described therein. My results over this fairly long period entirely support the conclusions reached by the authors of the article.—I am, etc.,

G. H. PEARCE, M.D., M.R.C.P.,
Medical Officer of Health.

Batley, March 7.

The Shortage of Nurses

SIR,—I think that your readers will agree that the medical profession could not exist and function without the aid of the nursing profession. Yet I submit that we are doing little or nothing to avert the Nemesis that will shortly fall upon, and paralyse, at any rate the smaller hospitals. I refer, of course, to the great and growing difficulty of recruiting nurses. I am aware that an Interdepartmental Committee is dealing with the subject, but these Government committees work all too slowly.

The subject is a vast one, but the chief troubles seem to be the lack of financial inducement to enter the nursing profession, and, even more than this, the very bad advertisement given to the profession by the conditions which exist in many hospitals. Every year a larger and ever-growing section of the community is treated in hospital, and hospitals can no longer claim to be regarded as charitable institutions, yet nurses are still exhorted to consider their work as a vocation—"they give their services to the poor and needy," etc. Nurses could be and should be better paid. This would serve two purposes: first, it would encourage recruiting; secondly, and this is perhaps even more important, it would enable a properly constituted central authority to enforce a sufficiently large yearly levy on the nurse's salary to ensure an adequate retiring pension—say, at the age of 50. This would go a very long way towards eliminating that dreadful incubus of the profession, the ageing matron, who can

¹ *Z. physiol. Chem.*, 1937, 248, 96.

Asthma and Sensitivity to Aspirin

SIR.—The problems in connexion with asthma seem to reach their peak in the aspirin-sensitive type. As originally noted by Dr. Alexander Francis and mentioned by him in the *Journal* of February 26 (p. 485), these people usually suffer from nasal polypi. Why is this so?

Although the aspirin-sensitive type is by far the most severe type of asthma one sees, such patients never touch aspirin from one end of the year to the other, except by some gross misadventure. Their attacks are almost always precipitated by a cough. Again, quite unlike other asthmatics, they may have the most dreadful asthma each night, requiring five or more injections of adrenaline to check it; yet by day the chest may be perfectly free from all adventitious sounds. I have only seen twenty-three of these cases in the last 1,000 asthmatics, mostly in women. In the more recent cases there has been found a *Staphylococcus citreus* in the nose. Probably the polypi are a true allergic manifestation according to von Pirquet. The most recent cases of all have responded very satisfactorily to vaccine from this organism, given in minute doses. They belong to Group III, by the differential sedimentation test.

Another peculiarity of those sensitive to aspirin is that, whereas anaphylaxis in animals is shown by a definite syndrome affecting many parts of the animal, with aspirin only one "shock" organ seems to be affected in each patient. An overdose of dust or pollen produces urticaria, asthma, and sneezing, but aspirin will cause only asthma in one patient—even in the gravest forms, in which the patient becomes unconscious, there is no nettlerash. In another, aspirin always produces urticaria but never asthma. Another is sick, always sick, after aspirin, again without asthma or urticaria.

With regard to the treatment of the polypi, sufficient should be "removed" from time to time to keep the airway clear through the nose, possibly with some improvement to the sense of smell, but with no hope of improving the asthma and a fair chance of making it worse.—I am, etc.,

London, W.1, Feb. 28.

FRANK COKE, F.R.C.S.

Ascorbic Acid in Urine

SIR.—I was interested to learn from the paper by Drs. Fleming and Burrows that sulphuric acid has been found unsatisfactory as a preservative of ascorbic acid in urine. It is perhaps of interest to note that in the course of a series of vitamin C estimations at present being carried out at this station we also have had cause to reject this method of preserving the ascorbic acid content of urine, but on rather different grounds from those given by your contributors. Attempts were made to preserve the urines by adding 5 per cent. by volume of dilute sulphuric acid (B.P.) sufficient to lower the pH to between 3 and 4. It was found that even in the case of fresh urines consistently higher reducing values were obtained by this method than in the case of urines treated with acetic acid. We then found that if a solution of 5 per cent. dilute sulphuric acid were added to a dichlorophenolindophenol solution under the same conditions as those obtaining in the actual titrations the colour of the dye was slowly discharged, showing that the acid has a destructive effect upon the dye. For this reason the use of sulphuric acid as a preservative has been discontinued.—I am, etc.,

E. A. G. GOLDIE, M.B., B.Ch.,
Civilian Medical Practitioner, R.A.F.

Royal Air Force Station, Peterborough,
Feb. 22.

Somatic Pain

SIR.—I wonder how many of your readers were, like myself, thrilled to the core by Sir Thomas Lewis's article in the *Journal* of February 12 (p. 321) on the subject of somatic pain. We now know much more than ever before of skin, muscle, and "web" pain: is it too much to hope that further investigation may add an equally, and perhaps more, important contribution to our knowledge of joint pain? The most interesting joints from this point of view are presumably unapproachable—namely, the sacro-iliac, and inter-vertebral and costo-vertebral joints. But many others are easily accessible, and knowledge of the nature of pain radiating from these might increase our knowledge of what happens in those less accessible. I hope Sir Thomas will forgive the hint, and, equally, that he may be induced to act upon it. It would help to solve the unknown answer to the question, "How does joint manipulation relieve referred pain?" That it does so in many cases is beyond doubt. As this is so, is it not possible that the relief is due to cessation of irritation of the sympathetic nerve supply to the joint? Our whole conception of the connexions of the sympathetic nervous system might thus be expanded and clarified, and another step be taken to afford scientific explanation of a clinical fact, the mechanism of it being still hidden from us.

Of Mr. J. H. Kellgren's article (*Journal*, February 12, p. 325) it may be hoped that, read in conjunction with Sir Thomas Lewis's communication, it will lead to a long-established (though modified) therapeutic measure being more widely adopted. To practitioners of physical medicine and to many others the facts about the nodal points of muscular sensitiveness with which he deals are common knowledge. Let us hope this article will change the "hundreds" into thousands, and that much unnecessary pain and incapacity will thus be saved. Unfortunately, Mr. Kellgren appears to ignore the possibilities of pressures, frictions, and needling in the treatment of the "nodal points" from which pain is referred.

There is one notable omission in this paper. When searching for the point at which to give the injection it may be localized as a rule far more accurately by faradism than by pressure. Indeed, not infrequently acute sensitiveness to faradism of pin-point dimensions will reveal the appropriate spot even when pressure fails to elicit any sign of sensitiveness. Moreover, if the spot indicated by pressure does not coincide with that indicated by faradism, it is wise to select the latter as the site for injection. Sometimes the sensitive area from which pain is radiated is too diffuse for injection with novocain or for treatment by pressure. In this event a very brisk reaction dose of ultra-violet light may either clear up the condition without further treatment or suffice so to diminish the general sensitiveness that the nodal point can be localized by faradism to a nicety. Finally, when the area involved is really widespread, a subcutaneous injection of oxygen will often prove successful when all other methods have been tried and found wanting. It is particularly efficacious when pain is marked as a result of "skin rolling."

One last word. Is there anything really new about the injection treatment of these nodal points? Formerly treatment by "needling" was a favourite prescription. The red-hot needle gave way to needling without heat; this tended to die away until revived by the use of the galvanic needle; and now we—in the kindness of our hearts—use a local anaesthetic. Is it the anaesthetic nature of the material injected, or is it the needling, that "does the trick"? Perhaps Sir Thomas can help us with

off in youth and increasing the number of its aged. Is it not madness to spend colossal sums on social improvements and rearmament if heavy taxation leads to a fall in the birth rate, which saps the strength of the country, while the keeping alive of the aged takes away money which should enable the young to have children?—I am, etc.,

St. John Clinic, Feb. 28.

LEONARD HILL.

Contraceptives and Fertility

SIR,—Not without reason did the ancients name the delicate arrangement of the ciliated epithelium of the cervix *arbor vitae*, a tree that the National Birth Control Association and its satellites would destroy root and branch in their adherence to, and advocacy of, highly acid chemicals and the application by septic fingers of various caps before or in the early days of matrimony. Quite apart from ethical, religious, or sociological reasons, surely they do not maintain that such fronded epithelium is likely to be unaffected by these irritants, and will accept the conclusive evidence and experience of Gardner Child (*Sterility and Conception*, p. 89); Beckwith Whitehouse (fourth edition of Eden and Lockyer's *Gynaecology*, p. 429); Blair-Bell (*Principles of Gynaecology*, p. 336); Meaker (*Human Sterility*, pp. 39 and 125); and others that such irritation gives rise to conditions which "make the endocervical mucus inimical to spermatozoa by creating a viscosity—such viscosity is a hostile factor, in that viscid secretions impose a barrier which spermatozoa are rarely able to surmount" (Meaker).

It was this condition which Mr. George H. Alabaster referred to and which goes on to the erosion and endocervicitis which is so commonly seen in patients who use contraceptives. Since the social, economic, and imperial policy of this country depends upon an increasing rather than a decreasing population, surely the promiscuous donation of advice to nulliparous young women is anti-social, however good the reasons may be for giving the same advice to parous women who wish to space their children. Only such advice, I understand, is given in the clinics of the Constructive Birth Control Society. Admittedly the problem is a thorny one, but it is not without interest to observe that orthodox Jewesses and Roman Catholics in the absence of hypoplasia are rarely found to be sterile. Why?—I am, etc.,

London, W.1. Feb. 25.

V. B. GREEN-ARMYTAGUE.

Miners' Nystagmus

SIR.—In your article (*Journal*, February 26, p. 465) which deals with the Departmental Report on Miners' Nystagmus you refer to my view that failure to work is caused by the breakdown of the man's ability to withstand the stresses of the mine—poor illumination and danger—and in contrast to this you go on to state that "in a large number of cases disablement is entirely due to ocular movements and the man is otherwise well."

I am very familiar with cases in which, at first sight, this may appear to be the case, but must point out that the observation that the man is "otherwise well," like every other observed fact, involves two elements—a fact, and an observer. It has been my experience that sufficiently prolonged and careful interrogation of these cases discloses that, with very rare exceptions, the apparently "well" man is the victim of a neurosis which arises either from the conditions of his employment or from some economic or domestic source. So often is this

search for neurosis successful, that one is tempted to think that in the remaining cases it may be the observer who fails rather than the neurosis which is absent. This view largely endorses the findings of Professor Millais Culpin, who has reported a series of thirty-six cases and whose further findings were outlined in a paper to the Royal Society of Medicine in 1933.

But even if it be taken that the pathogenesis of the ocular movements is itself physical and not psychological (personally I have an open mind on this point), I suggest that there is an extremely close relationship between the severity and distress on the one hand and the emotional state on the other, and I suggest that the determining factor in failure to work is psychological.

In one of my cases it was impossible to induce oscillation by any of the recognized means until, unexpectedly, a whistle in a speaking tube close to the man was loudly blown from an upstairs office. The man then gave a start and at once began to display oscillation.

In another case, a man aged 38, who appeared "well" apart from his eye movements, ultimately imparted the following information, which was only elicited with great difficulty and was not uppermost in his conscious thought. When he was 15 years old he had been walking along by himself in the mine when he had come across the body of a man who had been trapped and killed under a fall. This, he said, had upset him, but he had not allowed anyone to see how he felt, and had afterwards continued his work. More recently another man working in his proximity had received a seriously crushed back. The man's further statement—"As soon as I go down the pit I am finished straight"—was possibly associated with his mental state, and to describe a man as being, apart from eye movements, "otherwise well" would, I submit, constitute an incomplete observation of fact.

I further submit that the statistics quoted in my paper also indicate an important mental influence of economic factors.

Thirdly, among fifteen collieries of North Wales, one, and one only, remained completely free from certified cases of nystagmus during the ten-year period of my observations. This pit was not better lit than the others, though it used a good type of spirit lamp. There were no features which strikingly distinguished this pit from the others in the coal-field, except that the incidence of accident was extremely low. It was also noticeable that the ventilation system was particularly good, the seams were high, and also there was a particularly happy relationship between employer and employed; but it should also be said that this mine was situated at a considerable distance from all the others in the field and did not absorb many men leaving the other pits. It had been reported that some of the men in this mine did in fact show oscillation of the eyes, but the fact remains that no cases of disablement were recorded throughout the decade. The factors distinguishing this pit from the others were those capable of exerting a psychological rather than a physical effect.

It is not clear from the account in the *Journal* whether the Departmental Committee has followed the suggestion of the B.M.A. Committee in the particular mentioned on page 9 of the latter's report—namely, that the Medical Board should include "a physician with some knowledge of psychological medicine." If this advice has not been followed, it appears most regrettable. Personally I would have liked to hear that the Board would consist of a consultant psychologist and a physician with some special knowledge of the processes of mining; for I submit the general indications are that disability from the disorder does not particularly concern the department of the oculist.—I am, etc.,

Wrexham, March 2.

RAYMOND BROCK.

complaining of any ill effects he was put to bed and regarded as suffering from influenza. His temperature, however, continued to rise each day to 102° F. or 103° F., and since there appeared to be no change in his condition I was asked to see him after he had been in bed ten days. His temperature was then 102° F., but apart from this no physical signs were to be elicited.

On the strength of the history and the paucity of clinical findings I made a tentative diagnosis of a *Br. abortus* infection, and immediately started the patient on one tablet of prontosil album four-hourly. His blood was examined by Professor W. J. Wilson of Belfast, who reported that agglutination occurred with *Br. abortus* up to 1 in 2,500. After twelve days the temperature remained below 100° F., and the dose of prontosil was then reduced to one tablet eight-hourly; this was maintained for a further ten days. By this time the temperature was only rising to 99° F. every second or third day. The prontosil was then discontinued, and after four more days the temperature remained normal. At no time was the spleen palpable. Including the ten days that elapsed before I saw him the illness lasted altogether approximately five weeks, which is, I think, sufficiently short of the usual period to be noteworthy. In this case there was no sudden fall in temperature, such as Dr. Lloyd and Dr. Matthews have reported. The temperature, which was recorded four-hourly, gradually stepped down over a period of twenty-two days.

There is an impression among many medical men that drugs belonging to the sulphonamide group are highly toxic. It is interesting to note that a boy of 10 years took 675 grains of prontosil album in twenty-two days without showing any ill effects. The usual precautions regarding (a) sulphur intake and (b) agranulocytosis were of course taken.

On another aspect of this disease I would welcome information. I have a friend who a few years ago suffered from abortus fever for seven months. He would willingly have given his serum for use in this case. I have been unable to find out whether such serum has been used before. I have since heard, however, of a case of abortus fever which was admitted to a hospital in Belfast some years ago. This patient ran the usual temperature for about three weeks. He then accidentally got an injection of "normal cow serum," and from the following day his temperature remained normal. The doctor who told me of this case thinks that possibly the serum had been obtained from a cow which had recovered from abortus fever. As I now have two sources from which I can obtain serum I should be very glad to know if it has been previously used.—I am, etc.,

Lisburn, March 3.

W. A. PAGE, M.D.

Time for Midwifery

SIR,—Dr. John Elam (*Journal*, February 26, p. 485) is wrong in suggesting that I have not studied the Maternal Mortality Report for 1937. I have studied all the recent reports on that subject, and the more I study them the more convinced I am that my suggestion regarding the postgraduate training of practitioners who intend to practise midwifery is correct. How many of us would trust our wives to a man who had no more experience of midwifery than he had gained during his student days? There is a difference between "want of time" and "want of taking time." The man who has not enough time for midwifery should not practise it. There is no excuse for "not taking time." A man who has a sound training in midwifery will understand that parturition is a normal

physiological process and that the less it is interfered with the better. He will not let himself be hurried into interference either by the patient, her friends, or his golf appointment. He will know how to diagnose a position correctly, and when and how to apply forceps. "Failed forceps" cases will become less frequent. I do not agree with Dr. Elam that the conduct of the normal confinement is best left in the hands of the competent midwife. Two years ago my son was engaged to attend a woman. He diagnosed a breech position. The midwife (competent according to the health authorities) told the woman that my son was wrong. The result was that my son received a note cancelling the engagement. Time proved him correct. A year or two ago a patient of mine returned from a municipal home with a complete perineal tear. She had not been seen by a doctor. My partner tells me he has seen five other cases of the same kind in the last three years.—I am, etc.,

Birmingham, Feb. 26.

ROBERT ANDERSON.

SIR,—With reference to Dr. Elam's letters I am of the opinion that medical women are not always the best to attend obstetric cases, nor do I agree that they have more time at their disposal than men. In this county we have a very large number of well-informed medical men who practised obstetrics long before a county hospital service was available. They have done magnificent service in the past and have welcomed our hospital and emergency services.

I am also of the opinion that no man can efficiently practise his calling without having had sufficient training. The medical student of to-day has not enough obstetrical experience, though material available in many of our municipal maternity hospitals is not being utilized to anything like its full extent. The recently qualified man who has gone into practice on his own without having obtained sufficient experience in obstetrics is the one who is likely to find himself in difficulties. I can sympathize with this young man, who admits failure in the eyes of his patient if he calls in an experienced practitioner. The new Maternity Services (Scotland) Act, 1937, provides for a domiciliary service. Those who are to carry out the provisions of the Act must have a sufficient knowledge gained either before or immediately after graduation.—I am, etc.,

County Maternity Hospital,
Lanark, Feb. 28.

H. J. THOMSON.

Founders of British Otology

SIR,—It has afforded me great pleasure to read in the *Journal* of February 26 (p. 464) a recognition of the debt which British otology owes to James Yearsley, who is justly entitled to be considered as the first Englishman to establish our special branch of surgery upon a sound clinical basis. In an article on the foundations of British otology, published in the *Journal of Laryngology* for August, 1913, I pointed out that "at least six great names must endure as inseparable from the rise and growth of British otology—William Harvey, John Hinton, George Pilcher, Joseph Toynbee, William Wilde, and James Yearsley"—and I insisted that the work of the last-named foreshadowed much of what is the basis of modern treatment and prevention, because it was he who first stressed the connexion between deafness and diseases of the nasopharynx. He was the first to advocate the removal of tonsils (he removed those of my own father), and he nearly discovered adenoids. The soundness of his doctrines is to be found in his written works. The Yearsley family is an old one, and my tree goes direct

the answer. Certain it is that, when injection has failed, injection followed by a very free "needling" throughout the injected area will bring relief, and particularly if the area is subjected to a process of (not too vigorous) hammering of the area by blows from a mallet transmitted through a rod of wood protected by a felt pad.* Whether this treatment forces the injected fluid away from the spot "hammered" with sufficient force to stretch any adhesions that may have formed round the nodal point is a matter for speculation. The fact remains—it works.—I am, etc.,

London, W.1, Feb. 25.

JAMES MENNELL.

P.S.—Another problem for Sir Thomas Lewis. Can he tell us how the reaction dose of ultra-violet light diminishes sensitiveness? Is it due to chemical action and perhaps the formation of histamine?—J. M.

Referred Pains Arising from Muscle

SIR,—During the past two years I have used novocain injections in treating muscle, bone, and joint injuries. I therefore read Mr. J. H. Kellgren's article in the *Journal* of February 12 (p. 325) with great interest, and I should like to congratulate him on the careful and accurate recording of his cases. I have described the results obtained with this method of treatment in the *Journal of the Royal Naval Medical Service* (January, 1938, p. 48), and also recorded my finding that the results in cases of shoulder injury are very uncertain, this being almost certainly due, as Mr. Kellgren has shown, to the fact that referred and "true" pain are confused by the patient. With such careful records as Mr. Kellgren has kept this difficulty should soon be overcome. Mr. Kellgren has confined his article to muscle pains, but it has been found that bone, joint, and muscle injuries can all be relieved by novocain. I think that the discovery of this method of treatment should be credited to Professor René Leriche of Strasbourg, who as long ago as 1928 described this method in the treatment of sprains, and has since extended its application (*La Presse Médicale*, 1930, No. 25).—I am, etc.,

Dundee, Feb. 27.

WALTER GORDON CAMPBELL.

Chronic Littritis

SIR,—Dr. R. C. Webster is to be commended for directing attention, in his paper on chronic littritis (February 26, p. 448), to the dangers associated with the use of the hand syringe in the treatment of acute gonococcal urethritis. While in full agreement with this conclusion, I find it difficult to accept the pressure theory by which he explains this fact. He admits that the use of unusual, or too concentrated, solutions as irrigating media tends to produce chronic littritis, and this statement cannot be reconciled with the pressure theory advanced. It is inconceivable that the glands of Littre and the ducts leading from them to the urethra escape infection in acute urethritis, in spite of any valve-like action which might be postulated for the ducts in virtue of their tortuous path from the submucous layer to their openings on the surface of the urethral mucosa. I therefore submit that acute infection of the glands of Littre in varying degree is commonly associated with acute urethritis, and I believe that the production of chronic littritis, assuming a normal resistance on the part of the patient, is dependent on failure to promote and maintain adequate drainage of the infected glands and ducts. This failure

* Reference is made in the issue of February 26 (p. 488) by Dr. Stuart Goldhurst to the efficacy of this treatment as described by Dr. T. Stacey Wilson.

may arise through several causes, which include improper irrigation whereby the potential space of the urethra is insufficiently, or too seldom, adequately dilated, and also premature closing of the ducts consequent on fibrosis due to the use of too concentrated irrigating solutions, a second infection of the urethra, or unusually rapid resolution of the inflammation which, in some cases, may follow the use of the sulphonamide preparations. The prevention of chronic littritis therefore depends on the institution as early in the disease as possible of regular irrigations, using the proper concentration of a suitable solution at the optimum temperature (105° F.), and on ensuring that the correct technique of douche-can and nozzle irrigation has been demonstrated to, and is being practised by, the patient. Urethral lavage with the hand syringe cannot hope to achieve an adequate and even dilatation, nor can the irrigating fluid be maintained at the correct temperature.

The following figures from cases recently treated in Liverpool appear to support these views. In 132 patients with gonorrhoea chronic littritis developed in eleven; two gave a history of previous gonorrhoea, one reported for treatment six weeks after the appearance of the discharge, one had irrigated with a douche can at home without instruction or observation, one had difficulty in irrigating satisfactorily due to severe phimosis, and two had used a hand syringe. Again, of twenty-five cases of acute urethritis in which irrigations and sulphonamide were used concurrently from the beginning of treatment, twelve developed persistent chronic anterior urethritis; but of fifty-three cases in which sulphonamide was given after the patients had been irrigating for about a fortnight, only five developed chronic anterior urethritis. In all cases gonococci were demonstrated and syphilis excluded, and the diagnosis of chronic littritis was based on the persistent presence of threads in the first glass of the two-glass test, with palpable Littre's glands in cases in which the urine had been clear and the prostate and vesicles free from pus cells.—I am, etc.,

Liverpool, March 1.

SYDNEY M. LAIRD.

Treatment of Boils and Carbuncles

SIR,—I was much interested in Mr. John Hosford's article (February 19, p. 400). I have treated boils and carbuncles successfully by means of short-wave diathermy, and I think that this method deserves some recognition. The machine I use has a 6-metre wave-length, and I find that one treatment lasting five or seven minutes is sufficient to abort a boil in the early stages. If it is more advanced matters are brought to a head within about eight hours. I have also used x-ray therapy for boils, employing voltages varying from 90 kV up to 200 kV, delivering 200 r at the surface of the lesion. Short-wave diathermy is much more certain in its results. Carbuncles may require one or two treatments, but even large sloughing areas, 10 cm. or more in diameter, will respond to the treatment.—I am, etc.,

Glasgow, March 2.

S. D. SCOTT PARK.

Br. abortus Infection Treated by Sulphanilamide

SIR,—I should like to add the report of a third case of *Br. abortus* infection to those already described in the *Journal* by Dr. J. H. Lloyd (January 15, p. 145) and Dr. N. Matthews (February 26, p. 483). In January I was asked to see a boy aged 10. His mother had noticed that he was looking pale and out of sorts, and found that he had a temperature of 102° F.; as he was not

whose historic Minster he had been a member of the Governing Corporation under the foundation of Queen Elizabeth for many years.

Sir Kaye Le Fleming writes:

Batterbury was one of the last of what may be termed the old school of general practitioners. The advance of medicine and social evolution have made their mark on the conduct of medical practice more deeply in the last half-century than perhaps in any similar period of time. Beginning his career as a country practitioner, driving in all weather over rough country roads intersected by turnpike gates, Batterbury saw the introduction and steady development of modern surgery. Stage by stage he witnessed the advent of local hospitals, the discovery of x rays, the development of bacteriology with the use of vaccines and sera. The bicycle, telephone, and, later, motor cars replaced the messenger on foot or horseback, and relieved much of the physical strain of the country doctor's life. Such a life was bound to develop a fine clinical sense, which was the admiration of all his colleagues and the envy of not a few. Batterbury's quiet confidence and self-reliance and his outstanding knowledge of his work soon established him as the leading doctor of the district, and founded the large practice to which he devoted his whole life. He was the trusted colleague and loyal partner in the large firm which now carries on the practice. His single-hearted devotion to his work, and the large claims which it exacted, left him little time for outside interests except in the field of Masonry.

Always a staunch supporter of the B.M.A., he was president of the Dorset and West Hants Branch in 1889 and a regular attendant at its meetings, and gave every encouragement to the writer to serve the Association. He also held office as chairman of the Bournemouth Division in 1922-3. He was the perfect partner, wise in his counsel, rich in the wisdom of experience, sound and safe in consultation, and I look back with happy memory on a partnership of thirty-five years devoid of a single disagreement or misunderstanding. The great traditions of our profession were safe in his hands, and to men like Batterbury the whole profession owes a debt of gratitude too little recognized but none the less outstanding.

JOHN FREDERICK WALKER, M.B., J.P.

By the death of Mr. J. F. Walker, at the age of 63, on February 27, following an operation at the London Hospital, the British Medical Association loses a keen worker and loyal supporter and the borough of Southend-on-Sea a useful citizen and much respected and loved practitioner. In both these spheres of his activities his outstanding personality came to the fore at a comparatively early age.

Born in London, he was educated at King Henry VIII School, Coventry, and at the City of London School, where the early signs of his future oratorical powers were recognized by the award of the John Carpenter medal for elocution. From school he took up his medical studies at the London Hospital, where he was Buxton scholar and held the post of house-physician. While at hospital he was a keen association football player, and he was always proud of the fact that it was during his secretaryship of the club that "The London" won the inter-hospital cup for the first time in its history. In 1903 he settled in partnership at Southend-on-Sea, and it was here that his life's work lay. He soon acquired a reputation as the best type of family practitioner—

friend as well as medical adviser. His influence in civic affairs, particularly as they affected the local profession, was soon felt, and as honorary secretary of the South Essex Division of the Association he played an important part in the negotiations in connexion with the newly introduced National Health Insurance Act. In 1925 he was appointed to the Commission of the Peace for the borough. He also held the appointment of police surgeon, being the first to hold that post on the creation of the Borough Constabulary in 1913.

Walker's work for the Association was not confined to the South Essex Division, and in 1924-5 he was elected to the Council, and again in 1930-1. He was first chairman of the newly formed Charities Committee in 1925, and remained a member until 1935. He was particularly keen on this branch of the Association's work, and organized a plan for the collection of funds in the South Essex Division which might well be taken as a model by many other Divisions. He represented the Division at the Annual Representative Meetings in 1912, 1913, 1919, and 1925, and served on many other committees and sub-committees at headquarters. He was chairman of the Division in 1926, and at the time of his death was president of the Essex Branch. During the latter part of the war he became visitor for the Central Medical War Committee, with the rank of Deputy Commissioner of Medical Services, under the Ministry of National Service, and his services received special commendation in a minute passed by the General Purposes Subcommittee on November 27, 1918. From 1929 to 1933 he was a member of the Ministry of Health Joint Advisory Committee on Disciplinary Procedure.

In spite of his many activities he found time for recreation, and although taking to the game fairly late in his life he became a golfer of no mean order. Twice, in 1927 and 1933, he was elected captain of the Rochford Hundred Golf Club, and at the time of his death was one of its trustees. It was a bitter blow to him when arthritis of the hip, which attacked him in the last few years of his life, compelled him to give up the game about which he was so keen. All his life a staunch Conservative, he took a great interest in politics, and in 1935 he was elected chairman of the Southend-on-Sea Conservative Association. Here his powers of oratory were used to great effect, and in this sphere particularly his place will not easily be filled. As an after-dinner speaker and witty raconteur he earned a reputation second to none in the district.

He possessed a very human heart and a very sound judgment, and he will be greatly missed, not only by a wide circle of friends but by many devoted patients, and not least by his professional brethren in South Essex, to whom advice, so often sought, was always so freely given.

Dr. WILLIAM ALEXANDER YOUNG of Mukden died at his home in Edinburgh on February 20, aged 64. He graduated M.B., C.M. at Edinburgh University when 21. These are bald facts concerning an unusually brave and capable man of whom our profession has reason to be proud but of whom it knew little because he always shunned the limelight. A son of the manse, he went straight after graduation to the mission field in Manchuria, and after his thirty-three years' work there became a recognized authority on Chinese affairs. Because of the Boxer rising in 1900, in which he was stoned and nearly lost his life, he joined the Navy for a year, but returned to Mukden in 1902. During its siege in the Russo-Japanese War he succeeded in evacuating from it a party of friends, but returned to it for the sake of the refugees, and nearly died of typhus fever rampant there. He then worked at two

through the male line to the Wars of the Roses. Our ancestor, who held manors in Yorkshire, was an officer of the Wardrobe of King Henry VI. From him came the Gloucestershire branch, and in this branch James Yearsley was a first cousin to my grandfather (also a James), the latter belonging to the senior line. The tree shows descent in the male line from the Yorkshire Yearsley above mentioned through fifteen generations to my own son. James Yearsley was a man of fine presence and ready wit, and there are many amusing stories of him.—I am, etc.,

London, W.1, March 1. MACLEOD YEARSLEY, F.R.C.S.

Obituary

HAROLD SIMMONS, M.B., B.S.

Consulting Surgeon, Royal Victoria and West Hants Hospital, Bournemouth

We have to record with much regret the death on February 22 of Dr. Harold Simmons of Bournemouth. Although in his seventy-sixth year he had continued in the active work of an extensive general medical practice, doing a full day's work with keenness and enthusiasm, until illness laid him aside a fortnight or so before his death. He had qualified L.S.A. in 1884, M.R.C.S. in 1885, L.R.C.P.Lond. in 1887. In 1894 he proceeded to the M.B., B.S.Durh.; in 1895 to the D.P.H. of the English Conjoint Board. He was a student of the Bristol Medical School and of the Middlesex Hospital. Before settling in practice he occupied the posts of house-physician at the Middlesex Hospital, resident medical officer at the Royal Hospital for Diseases of the Chest, City Road, and assistant medical superintendent of the Fulham Infirmary. For an interval he acted as medical officer on ships of the Union Castle and P. and O. shipping lines.

Dr. Simmons had practised in Bournemouth for forty years, being for the greater part of that time associated with the Royal

Victoria and West Hants Hospital, first as assistant surgeon, which post he resigned shortly after the war, being then appointed a consulting surgeon to the institution. Before the amalgamation of the Royal Victoria Hospital, Poole Road, with the Boscombe Hospital he was medical officer to the out-patient department of the former. During his long association with the hospital he took an active part not only in the professional side of his work but also in the management of its affairs. Up to the last he was a member of the house committee and of the medical council, to both of which he frequently contributed from his wisdom and long experience. Soon after qualifying he became a member of the British Medical Association, and he had been chairman of the Bournemouth Division. He was a member of the Bournemouth Medical Society; and from the start of the movement was a keen, attentive Rotarian. An enthusiastic motorist, he was one of the original members of the Hampshire Automobile Club founded in the year 1906, being honorary treasurer of the Southern Division of the club. For a great many years Harold Simmons was police surgeon for the County Borough, being frequently called upon in the

course of his work to give medical evidence in the cause of justice. As a police witness he was exact, thorough quite unprejudiced; could always be relied on to adhere to facts and, when called on, to offer expert medical guidance which was scientific, just, and eminently fair. What will, perhaps, remain as a delightful memory to friends and colleagues alike was the unfailing sense of humour which he possessed as well as the wisdom he brought to bear in all his relations with his colleagues—by whom he was held in the highest respect. At the funeral service former patients joined with members of the medical profession, representatives of motoring organizations and of public bodies to pay their grateful tribute to his memory. The esteem in which he was held was evident from the great number who attended, many in advanced years. Much sympathy will be felt for his widow, who had been his constant companion and help for more than forty years, and for his daughter and his son, himself in medical practice in Bournemouth.

S. W. S.

Dr. L. A. Weatherly writes: I first knew Harold Simmons some fifty-five years ago when he was a student at the Royal Infirmary, Bristol, near which I had then been in practice some twelve years. Thirty-one years ago, when I came to Bournemouth, he was one of seven medical men who gave me a kindly and helpful welcome. They were all my juniors and all are now gone except one. During those thirty-one years I have frequently met Harold Simmons. We have never had an unfriendly word, and if I were asked to give my opinion of him as a medical practitioner I, with all sincerity, should say that from my experience of him I looked upon Harold Simmons as the embodiment of medical ethical integrity.

The Rev. W. Yorke Batley writes: My friend Harold Simmons was a representative type of the old-fashioned family doctor, which is perhaps becoming rarer in these days of specialized scientific medicine. As a doctor he was concerned not only with the particular ailment but with the whole personality of his patients, and all his knowledge and his sympathy were ungrudgingly offered them. The consequence was that, as they often put it, they really felt better when he visited them. Speaking as a layman I should say that his cheery, expansive personality, combined with a real clinical flair and an intense personal interest in his patients, gained and kept for him their complete confidence and persistent affection. He retained an open and receptive mind to modern medical and scientific developments to the very end of his long life. Every year he attended refresher courses at the Middlesex Hospital. His profession was his hobby as well as his livelihood, and he dreaded the coming of a time of retired leisure.

GEORGE HENRY BATTERBURY, M.D.

We regret to announce the death on March 3 of George Henry Batterbury of Wimborne after a period of sixty years' practice in that town. Born in 1850, he was educated at King's College, London, and entered the Medical School in 1869, where he had a distinguished career as Warneford prizeman and senior scholar. Taking his M.R.C.S. in 1873, he was house-physician in 1874 and medical registrar in 1875. In the London M.B. examination of the same year he was awarded the University scholarship and gold medal in medicine and the gold medal in obstetrics. From hospital he went direct to Wimborne, where the rest of his life was spent. The funeral service was held on March 7 at Wimborne, of

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on February 26 the following medical degrees were conferred:

D.M.—G. R. P. Aldred-Brown (*in absentia*), J. Wright.
B.M.—D. M. T. Gairdner.

UNIVERSITY OF CAMBRIDGE

Professor William Lawrence Bragg, D.Sc., F.R.S., has been elected to the Cavendish Chair of Experimental Physics in succession to the late Lord Rutherford. Professor Bragg is the son of Sir William Bragg, O.M., P.R.S., and held the Langworthy Chair of Physics in the University of Manchester from 1919 to 1937, when he was appointed Director of the National Physical Laboratory.

The following have been examined and approved for the degree of M.Chir.: P. H. R. Ghey, D. N. Matthews, W. F. Nicholson.

UNIVERSITY OF LEEDS

Dr. W. E. Adams has been appointed Lecturer in Histology.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—P. H. Beamish, G. H. L. Bullmore, P. C. Conran, A. W. Frankland, S. J. Nathan, J. R. Rose.

MEDICINE.—F. E. Buckler, E. E. Bullock, G. G. O. Evans, J. B. Good, M. W. Hemans, I. M. Monare, B. Oppenheim, E. S. Reed, A. T. Rogers, G. L. Young.

FORENSIC MEDICINE.—A. Backman, F. E. Buckler, E. E. Bullock, J. B. Good, M. W. Hemans, B. Oppenheim, E. S. Reed, A. T. Rogers, G. L. Young.

MIDWIFERY.—P. H. Beamish, G. E. N. Bird, F. P. S. Malone-Barrett, B. Oppenheim, A. Smith, B. W. S. Spurgin.

The Diploma of the Society has been granted to P. H. Beamish, E. E. Bullock, G. G. O. Evans, A. W. Frankland, J. B. Good, S. J. Nathan, E. S. Reed, A. T. Rogers, and G. L. Young.

The Services

HONORARY PHYSICIAN TO THE KING

Air Commodore Harold Edward Whittingham, C.B.E., has been appointed an Honorary Physician to the King, vice Air Vice-Marshal Sir Alfred William Iredell, K.B.E., C.B., who has relinquished his appointment on retirement.

DEATHS IN THE SERVICES

Surgeon Captain EDMUND CORCORAN, R.N. (ret.), died at Devonport on February 24, aged 79. He was educated in the school of the Royal College of Surgeons in Ireland at Dublin, and took the L.R.C.P. and S.I. in 1880. He entered the Royal Navy soon afterwards, attained the rank of fleet surgeon on February 11, 1900, and surgeon captain on January 6, 1914. He served through the war of 1914-18, receiving the medals. He was in receipt of a Greenwich Hospital pension.

Squadron Leader DAVID EDMUND STODART, D.S.O., D.F.C., R.A.F. (ret.), died at Brighton on February 26, aged 55. He was born in Victoria, Australia, on July 31, 1882, the son of D. E. Stodart, J.P., and was educated at Edinburgh University, where he graduated M.B., Ch.B. in 1910, studying afterwards in the Middlesex and London Hospitals. In 1912 he took up flying, and was appointed second lieutenant in the Royal Flying Corps, Special Reserve, on May 17, 1913. In February, 1914, he was appointed Flying Officer in the R.F.C., and went to France with No. 3 Squadron in August, 1914. He served throughout the war, chiefly in France, later at Aden and in India; was thrice mentioned in dispatches, and received first the Distinguished Flying Cross and later the

D.S.O. The latter award was recorded in the *London Gazette* of September 21, 1918, when it was stated that, while in command of a flight of the Royal Air Force, all the other officers in the flight were incapacitated through sickness or wounds, and he carried out their duties in addition to his own administrative work as commanding officer. "In a period of twenty-one days this officer was thirty-seven hours in the air, performing all the duties of an entire flight, a record which it would be difficult to surpass." He was placed on the retired list on March 1, 1931, and became assistant physician in the dermatology department of the Middlesex Hospital. In 1934 he competed in an air race to Melbourne, coming in sixth.

Medico-Legal

THE DEFENCE OF INSANITY

From time to time the criminal courts remind us of the wide gap that exists between the legal view of insanity and the knowledge gained by psychiatrists in the century which has elapsed since the formulation of the "rules in M'Naghten's case." A man recently charged at the Old Bailey with the murder of an elderly woman in a fit of temper pleaded that he was insane when he did the act. The evidence showed that he gave himself up, saying that he had killed two women, and confessed that after he had killed the elder a girl of 12 had come in and he had tied her up and stabbed her with a sharp poker. (He was not charged with the second crime.) His conduct had been peculiar, and one of his grandmothers had died insane. The medical officer of the prison said that the man was sane, and that he could not tell whether he had been sane or insane at the time of the offence. Dr. Denis Carroll said that he thought the man would be certifiably insane in about a year. Lord Hewart, the Lord Chief Justice, said in his summing-up that few things surprised him more than the apparent levity with which juries were sometimes asked to find a fellow creature insane, with all the consequences which being found to be a criminal lunatic involved. (The consequences of being found to be a sane murderer are different but not more desirable.) The same defence was raised by the "Felixstowe" murderer, the mate of a barge who shot his skipper. Counsel on his behalf sought to prove that he was suffering from *mania à potu*, or acute insanity due to a drinking bout. Lord Hewart, as president of the Court of Criminal Appeal, said on February 21 that the defence of insanity requires three things: (1) that at the material time the offender was suffering from a disease of the mind; (2) that because of that disease of the mind he was suffering from a defect of reason; and (3) that because of that defect he either did not know the nature of his acts or did not know that they were wrong. In the Felixstowe case, he said, the so-called defence of insanity did not even begin to establish any one of those three things.

Without the whole of the evidence before us it would be improper even to hint that a wrong decision was reached in either of these cases. The Lord Chief Justice is frequently reported as demolishing the insanity defence with the hard cudgel of the M'Naghten rules. This is his duty, and in doing it he invariably displays absolute fairness. It does, however, seem anomalous that the law of criminal responsibility should leave out of account altogether the grave contributions which mental disorder makes to the commission of an act of violence, and the extent to which it often destroys real responsibility without bringing the patient within the M'Naghten rules. To the enlightened medical mind of to-day the act of murder is more often than not the culminating explosion, or crisis, of a long series of events for which the murderer is only in part, and sometimes hardly at all, responsible. Our civilization has not yet quite grown out of retributive human sacrifice.

branch hospitals and travelled widely in Manchuria doing dispensary work, and in 1915 joined the staff of Mukden Medical College, founded by Dr. Christie, as many younger men had left for the great war. Again in 1922 he risked his life in an endeavour to stop the civil war between North and South China—and succeeded. On Christie's retirement he became manager of Mukden College, and there lectured on public health, a job for which he had qualified himself by taking his D.P.H. while on furlough in 1911. Under him the College steadily expanded, and when he came home a few years ago for the sake of his children's education he succeeded Christie as secretary to the College. He was untiring and resourceful in his efforts for it, bought an old motor car for £20 and travelled the length and breadth of Scotland on behalf of the Manchurian work, and was specially pleased when he got the licensing bodies at home to recognize Mukden Medical College as an authorized teaching institution for students. He had a statesmanlike vision, and it was no surprise to his intimates that he became special correspondent for the *Manchester Guardian*, and was employed to lecture on Far Eastern affairs to the four Scottish universities. For the latter purpose he made ingenious jigsaw maps of his own design. By his later lectures he raised more than the £4,000 required for the Christie Memorial Chair. But his heart was in Manchuria, and, perhaps all the more because he bemoaned the seizure of the country by the Japanese, he had made up his mind last year to return to the beloved land of his adoption. Notwithstanding the great gifts for which all admired him, and his forceful personality, he was the humblest of men.—J. A.

Dr. JOHN YOUNG MACFADYEN, M.B.E., who died suddenly at the age of 56 on Christmas Eve, 1937, in Charlottetown, had been for the last twenty years a prominent resident in the British West Indies. He was a graduate of Prince of Wales College and Queen's University, and had served for twenty years as medical officer in the Colonial Service in the British West Indies, residing latterly on the island of Nevis. On several occasions he had acted as Colonial Administrator, and in recognition of his services he was created M.B.E. in the New Year Honours in 1930. Dr. Macfadyen joined the British Medical Association in 1925, and belonged to the Leeward Islands Division. He is survived by his widow, one brother, and one married sister.

Dr. JAMES HENRY GILBERTSON of Hitchin, Herts, died suddenly on February 22 at the age of 77. A student at St. Bartholomew's Hospital, he obtained the M.R.C.S. in 1883 and the L.R.C.P. in 1885. In addition to carrying on a busy practice he rendered fine service to the St. John Ambulance Brigade, of which he was ultimately elected an honorary life member and created an Officer of St. John of Jerusalem. He had held the appointments of medical officer of the second district in Hitchin and of the German Convalescent Hospital in that town. He was for some years honorary consulting medical officer to the North Hertfordshire and South Bedfordshire Hospital. He joined the British Medical Association in 1892, and was a representative at the Annual Meetings at Aberdeen in 1914 and London in 1916.

Dr. GEORGE DAVID KNIGHT, who died in Streatham on January 30 after a brief illness, had been a member of the British Medical Association for fifty-one years. Born in Aberdeen in 1861, he received his medical education in that city and in Edinburgh, graduating M.B., C.M. Aberd., in 1882, in which year he was bracketed "student with the highest honours" with Dr. T. Wardrop Griffiths, who is now emeritus professor of medicine at the University of Leeds, their percentage of marks in all their final examinations averaging 95. Dr. Knight proceeded M.D. in 1893, again with the highest honours, his thesis being an original study of movable kidney and

intermittent hydronephroses. He then came to London to join Dr. Walter Verdon in practice at Brixton, later removing to Streatham. Highly esteemed by his colleagues, he carried on a large general partnership practice in Brixton and Streatham, and was for some time a medical officer to Brixton Dispensary. He was appointed a Justice of the Peace, and in that capacity had much to do with the care of mental cases, in institutions and elsewhere. Endowed with exceptional professional skill and knowledge in many branches of medicine, his kindly nature and firm integrity won him very many friends in private as well as professional life. In his earlier years he had taken a keen interest in politics, being a strong Liberal in outlook.

By the sudden death at the age of 58 of Dr. JOSHUA BOWER DALTON on February 23 the staff of the Leicestershire County Council have lost a good friend and a very valuable colleague. In his capacity as assistant school medical officer Dr. Dalton was a familiar and popular figure to the school teachers in the county, and his death will be felt very keenly by them. Graduating M.B., Ch.B. at Manchester University in 1905, he was shortly afterwards appointed senior house-surgeon at the Crumpsall Hospital, Manchester. After various other appointments he held a commission in the R.A.M.C. during the late war, and as a result of this service he suffered from an eye defect which, though a distinct handicap, he was able to overcome. He was appointed to the staff of the Leicestershire County Council in 1921, and during the past seventeen years his work brought him into contact with a large proportion of the school population in the county, by whom he was looked upon not only as the school doctor but as a friend.

With the death of Dr. JOHN MACWATT, J.P., of Duns, Berwickshire, on February 24 there passed one of the most widely known medical practitioners in the South of Scotland. He received his medical education in Edinburgh, where he graduated M.B., C.M. in 1878. He then held the posts of house-surgeon to the Royal Maternity Hospital, Edinburgh, and the Edinburgh Royal Infirmary; he was also resident gynaecological assistant to the Glasgow Royal Infirmary. Later he settled in Duns, succeeding his father in practice; he held numerous public health appointments, including those of medical officer for the borough of Duns and for several parishes in the vicinity and police surgeon. When he retired in 1934, after fifty years' service, he was presented with a cheque for £500 as an expression of the gratitude of a large population among whom he had worked and of the very high esteem in which he was held. Dr. MacWatt joined the British Medical Association in 1899, and remained a member until his death. He took great interest in horticulture, and was the author of a book on *The Primulas of Europe*.

Dr. JOHN HARMER DREW of Weston-super-Mare died on February 27 suddenly at his residence in that town at the age of 56. He received his education at St. Thomas's Hospital, and graduated M.B., B.S.Lond. in 1905, obtaining the diplomas M.R.C.S., L.R.C.P. in the same year. He proceeded M.D. four years later. His first appointments included those of house-surgeon to St. Thomas's Hospital, house-surgeon to out-patients and senior casualty officer, and clinical assistant in the Ear Department in the same institution, resident medical officer to the West London Hospital, and resident surgical officer to the North Staffordshire Infirmary and Eye Hospital. During the war he held a commission as captain R.A.M.C., and was a surgical specialist in the British Expeditionary Force. At Weston-super-Mare he was physician to the General Hospital, and carried on a busy general practice. He joined the British Medical Association in 1911, and was a member of the East Somerset Division.

EPIDEMIOLOGICAL NOTES

Small-pox

Small-pox was introduced into this country on Friday, March 4, when the P. and O. liner *Cathay* arrived at Tilbury with a patient suffering from an attack of the severe type of small-pox (variola major), from which he died seven days after arrival. An appeal by broadcast on the same evening was made requesting all passengers who had left the ship to communicate forthwith with the medical officer of health in the district in which they were staying. A case of small-pox, apparently of the mild form (variola minor), has been notified at Leighton Buzzard in a girl aged 5 years. The diagnosis has been confirmed since admission to hospital.

Typhoid Fever

There have been 42 cases to date in the outbreak of typhoid fever in Somerset, with 7 deaths. In Pembrokeshire an additional death from typhoid occurred last week, bringing the total number to 10.

Diphtheria and Scarlet Fever

Diphtheria continues to decline slightly in all five areas from which notification returns are made, but the numbers notified are still in excess of the median value for the last nine years for England and Wales, and very much in excess of the figures for the corresponding week last year, which were lower than the median value. In London the number is slightly less than in the corresponding week last year and than the median value for the last nine years. On the other hand, scarlet fever appears to be on the increase in England and Wales and Northern Ireland, while in Scotland—459 against 490 last week—and in Eire—90 against 100 last week—there has been a decrease. The increase of notifications in England and Wales is due more to a general rise over a wide area than to the presence of local outbreaks or epidemics. Thus in Devon there were 26 (16) notifications, of which 8 (1) occurred in Paignton; in Durham county there were 107 (90), of which 13 (8) were in Chester-le-Street; in Kent 72 (46) cases were notified, the increase being scattered over the whole county; in Lancaster there were 359 (97); in Liverpool 93 (80); in Manchester 73 (59). In Surrey there were 64 (43) notifications, the increase being scattered over the whole county. The figures in parentheses denote the numbers notified in the previous week. During the same week there were 198 cases in London, a number which remains less than the median value of 250. During the week under review there were no deaths from scarlet fever in London, Dublin, and Belfast. While there was a general decrease in the notifications in Scotland as a whole, 190 cases were notified in Glasgow, an increase of 2 over the previous week, with 1 death; in Edinburgh there were 50 cases (an increase of 7 over the previous week).

Measles

An increase in the numbers of cases of and deaths from measles has to be reported in the week under review: in the Great Towns 50 deaths were recorded compared with 31 in the previous week; of these 13 occurred in London, 2 in Manchester, 1 in Liverpool, 3 in Salford, 3 in Wigan. Details are available of the spread of the London epidemic: thus, 1,801 cases of measles were reported in the L.C.C. elementary schools, compared with 1,551 in the previous week, and the daily admissions to the L.C.C. fever hospitals were 68, compared with 61 for the previous week. Notifications for Bermondsey, Shoreditch, Southwark, and Stepney for the week under review—that is, ending February 26—are 38, 11, 178, and 42 respectively. In Scotland 1,653 cases were notified compared with 1,691 in the previous week: the figures for Glasgow being 1,264 (19), Edinburgh 112 (3), Paisley 118, Dundee 26,

Aberdeen 15. The figures in parentheses denote deaths. In Northern Ireland there were 259 cases, compared with 384 in the previous week: the figures for Belfast were 281 as against 362, while the deaths were 17, compared with 20 in the previous week. During the week 4 deaths from measles were recorded in Dublin.

Typhus in Morocco

Although typhus prevails in endemic form in Tunis, Algeria, and Morocco, returns received show that there was a noteworthy increase in the incidence in these countries during the winter of 1936-7. This winter the increase has been greatest in Morocco, the epidemic starting in late November or early December in Marrakesh. At the beginning of December, although the actual number of cases reported had not been large, the authorities recognized the danger of a rapid spread in a town of the type of Marrakesh, and made arrangements for the vaccination of large numbers of the native population. It was claimed that by the middle of January over 150,000 had been vaccinated. It was stated that the vaccination is not employed for Europeans as they do not stand it well, and it is noteworthy that the incidence of the disease among Europeans has been relatively high. The accompanying table shows the incidence in the Marrakesh

Typhus in Marrakesh District

	9/12/37	16/12/37	23/12/37	30/12/37	6/1/38	13/1/38	20/1/38	27/1/38	3/2/38	10/2/38	17/2/38
Cases	183	182	267	150	3	130	106	93	100	148	134
Deaths	22	17	14	66	0	41	30	11	16	20	19
European cases	4	9	11	0	1	8	9	24	7	16	6
European deaths	—	1	1	2	0	2	3	2	8	3	1

district week by week. The majority of cases occurred in the district round Marrakesh, the figures received to date for the town of Marrakesh being 65 cases in December and 75 cases in January. On January 7 it was reported that a focus had appeared at Taroudant and in surrounding native encampments. Two fatal cases occurred in British subjects in this town.

Casablanca is also affected, the number of cases reported in the area during December being 78 and during January 173. Of these only 6 and 15 respectively occurred in the town of Casablanca itself. On January 12, however, it was reported that there was a serious outbreak in the town. No actual figures are available up to date, but it is stated that the authorities regard the situation with apprehension and are inaugurating extensive vaccination and other precautionary measures.

During January and the first half of February, 24 cases were reported in Fez. It is stated that a number of these are in persons coming from Marrakesh and other parts of Morocco.

On the occasion of the International Congress in Budapest in 1909 the International Medical Postgraduate Committee was formed. This committee held its second session during the International Medical Congress held in London in 1913. In August, 1937, an international medical postgraduate congress was held in Berlin, at which forty-four nations were represented, and the organization of an International Medical Postgraduate Academy in Budapest was decided upon. The next session will take place on April 24, 1938, when a series of lectures will be delivered by foreign savants under the heading "Research and Postgraduate Training." The arrangements are in the hands of the Hungarian Medical Postgraduate Committee, under the presidency of Professor Emile de Grösz. Address: Budapest, VIII, Üllői-ut, 26.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended February 26, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in Eire. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases ; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1929-37 (Median Value Corresponding Weeks)

(iii) 9

* 231 cases in Belfast alone.

† After October 1, 1937, puerperal fever was made notifiable only in the Administrative County of London.

‡ Deaths from puerperal sepsis.
§ Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Vaccination Regulations at Woolwich Arsenal.—On March 1, in reply to Mr. Leach, Mr. HORT-BLISHA said that instructions would be issued that, except in the event of a small-pox epidemic, persons under 21 years of age were not in future to be required to be vaccinated, or revaccinated before entering civilian employment at the Royal Arsenal, Woolwich, or other War Department establishment in this country. Similarly, in the case of boys enlisting in the Army schools, vaccination or revaccination would not be required on enlistment or entry.

Birth Rates in Certain Occupational Groups.—Sir KINGSLEY WOOD said on March 3 that the Registrar-General's report upon occupational birth rates in 1931 was not yet complete. He could give certain advance figures for England and Wales as follows:

Occupational Birth Rates, 1931

	Crude live-birth rate per 1000 married males under 55 years of age
All married males (including unoccupied)	
under 55 years of age	95.9
Clergymen (Anglican)	70.5
Teachers	59.9
Professional occupations (excluding clerical staff)	73.5
Social Class III, skilled workers	95.3
Social Class V, unskilled workers	122.2

Notes in Brief

During 1937 extensions of stay were granted to 813 foreign professional men and women who had arrived during the last three or four years. These included sixty-six dentists and 181 doctors, and nearly 300 research workers.

Mr. W. S. Morrison hopes that legislation to give effect to the proposals contained in the Government's White Paper on milk policy will be introduced shortly after the Easter Recess.

Only the Corporation of Sheffield has by a local Act power to deal generally in milk. Five other local authorities have a limited power to sell prepared milk for infants.

Medical News

The Tavistock Clinic, Malet Place, W.C., announces with regret that owing to illness Professor Jung will be unable to give the four seminars at the Clinic which were to have been held on April 4, 5, 7, and 8. Professor Jung has had to cancel all his engagements, but hopes, if his health permits, to carry out the programme originally arranged during the week October 3-7.

The annual dinner of the Medical Superintendents' Society will be held on Saturday, March 19, at the Langham Hotel, London, W., at 7.15 p.m.

A meeting of the Society of Medical Officers of Health will be held at 1, Thornhaugh Street, Russell Square, W.C., on Friday, March 18, at 5 p.m., when there will be a discussion on "Hospital Policy in Relation to Preventive Medicine," to be opened by Dr. Arthur Massey and Dr. James Ferguson.

The next clinical meeting of the Society of Radiotherapists will be held at 11, Chandos Street, W., on Friday, March 18, when there will be a discussion on "Methods of Measuring and of Recording Dosage," to be opened by Drs. Stebbing, Paterson, Windeyer, and Clarke.

A meeting of the Chelsea Clinical Society will be held at the Hotel Rembrandt, Thurloe Place, S.W., on Tuesday, March 15, at 8.30 p.m., when Dr. A. F. H. Coke will open a discussion on "Sedimentation Tests in Rheumatism." The meeting will be preceded by dinner at 7.30 p.m.

On Saturday, March 26, at 8 p.m., a demonstration of men's and women's recreative gymnastics will be given in the Albert Hall, London, under the auspices of the Central Council of Recreative Physical Training. Lord Stanhope, President of the Board of Education, will speak, and Lord Aberdare will take the chair. Tickets at various prices may be had from the Anglo-Swedish Society, 10, Staple Inn, W.C.1.

The sixty-second congress of the German Society of Surgery will be held in the Langenbeck-Virchow House from April 21 to 24. A conjoint meeting with the German Society for Orthopaedics, Industrial Accidents, and Insurance Medicine will be held on April 22.

The German Society for Internal Medicine will hold its fiftieth annual meeting from March 28 to 31 at Wiesbaden in conjunction with the German Society for the Study of Children's Diseases, under the presidency of Professor Assmann of Königsberg. The following subjects will be discussed: examination of cardiac function, function and diseases of the suprarenals, vitamin B₂, and acute inflammatory diseases of the central nervous system. Further information can be obtained from Professor Assmann, Schubertstrasse 19, Königsberg.

The February number of the *Journal of Nervous and Mental Disease* publishes Paul Schilder's "Psychoanalytic Remarks on Alice in Wonderland and Lewis Carroll." When his paper condemning this children's classic as a sadistic fantasy was read before the American Psychoanalytic Association in December, 1936, it provoked a storm of discussion in the newspapers.

The January issue of the *Medico-Legal and Criminological Review* has appeared in a new shape which is easy to handle and pleasant to the eye. It is proposed in the future to increase the scope of this journal, which in addition to publishing the papers read before the Medico-Legal Society will include articles of general interest to members of both the legal and the medical professions.

The February issue of the *Bulletin de l'Office International d'Hygiène Publique* contains articles on yellow fever by Colonel S. P. James, president of the Yellow Fever Committee, Professor Ricardo Jorge, the delegate of Portugal, Dr. van Campenhout, delegate of the Belgian Congo; and on chronic rheumatism by Drs. R. J. Weissenbach and F. Françon of the French Ministry of Health.

A dramatized life of Oliver Wendell Holmes, "an American of many attainments," was broadcast by *Cavalcade of America* on February 9. The first scene introduces him as a law student of 21 at Harvard, writing his stirring poem "Old Ironsides," which aroused public sentiment, saved the most famous ship in the history of the U.S. Navy from being scrapped, and brought him national fame. He is next depicted battling with his own profession over the contagiousness of puerperal fever. We meet him again at the "Mutual Admiration Society," the Boston Saturday Club, which the "Autocrat of the Breakfast-Table" enchanted with his wit and urbanity. The play closes with Holmes reading his last poem at the breakfast given in honour of his seventieth birthday.

The Léon Bernard Foundation of the International Union against Tuberculosis announces that the biennial prize of 2,500 francs in memory of Professor Léon Bernard will be awarded in 1938. The subject for competition is "Social Aspects of Tuberculosis." The articles, which must be written in French or English and not exceed 10,000 words, should be sent to the secretary of the International Union against Tuberculosis, 66, Boulevard Saint-Michel, Paris VI, before May 1.

The King has granted Dr. Charles Albert Bentley, C.I.E., authority to wear the Insignia of Commander of the Order of the Nile, conferred upon him by the King of Egypt in recognition of valuable services.

Sir Harold Gillies has been nominated a corresponding member of the Berlin Medical Society, before which he read a paper on plastic surgery on February 9.

March 5 marked the centenary of the birth of Gustav Theodor Fritsch, who died on June 12, 1927, the collaborator with Hitzig in the discovery of the motor cells of the cerebral cortex in 1870.

The Yugoslav State has allotted a sum of four million dinars to the Yugoslav Society for the Scientific and Social Campaign against Cancer to enable a cancer institute to be formed at Belgrade.

Medical Notes in Parliament

The second reading of the Collecting Charities (Regulation) Bill was set down in the House of Lords for this week. On March 8 the Blind Persons Bill and the Population (Statistics) Bill passed through committee. The Dogs Act (1871) Amendment Bill (which provides that there should be an appeal from a court of summary jurisdiction to Quarter Sessions against an order for the destruction of a dog) was read a second time in the House of Lords on March 8, as was the National Health Insurance (Amendment) Bill.

The House of Commons discussed defence policy and Supplementary Estimates for Palestine and Colonial Services. The Army Estimates were also to be considered.

The Housing (Financial Provisions) Bill passed through committee in the House of Commons on March 3. On March 7 the Registration of Stillbirths (Scotland) Bill was read a second time, and sent to a standing committee.

A New Borstal Institution

In Committee of Supply in the House of Commons on March 1, on the Vote for Prisons in England and Wales, Sir SAMUEL HOARE said that a supplementary estimate was required for the provision of another Borstal institution, which was needed at once. It was proposed to take over the former London County Council centre for the unemployed at Hollesley Bay, Suffolk. It had been found that their efforts to increase the self-reliance and feeling of responsibility of the boys succeeded better if they dealt with them in small groups. At Hollesley Bay it was proposed to divide the boys into four or five units, each of them run on what was called at schools the "house" system, and all of them open to the country and not enclosed by high walls. There would eventually be about 300 boys at Hollesley Bay, but it was proposed to start on a smaller scale. It was desirable not only to get away from the old penal conditions but from the old penal terminology.

After debate, Mr. GEOFFREY LLOYD said that there would be no steps taken for psychological treatment at the new colony, for that work was centralized in the boys' prison at Wormwood Scrubs. The Home Office expected a report to be made very shortly on that work, when the whole subject would be reconsidered. Although they all knew now that a certain number of specially difficult cases did respond to psychological treatment in an extraordinary way, there were failures—as must be expected. Most of the boys did not need psychological training, but would respond to the ordinary common-sense instructional methods that were used at the Borstal institutions. There was now a scheme under which a proportion of the housemasters in Borstal institutions—and this would apply to the colony—were being trained, at the Institute of Industrial Psychology, in vocational guidance. They would have to that extent psychological training, which would be useful. The Home Office welcomed this new colony as a place where experiments could be carried out, notably in the direction of increased responsibility for the boys.

The Vote was agreed to.

Registration of Stillbirths in Scotland

Major NEVEN-SPENCE introduced in the House of Commons on March 2 a Bill to provide for the registration of stillbirths in Scotland, and it was read a first time. Its backers included Dr. Howitt and Mr. Graham Kerr. Major Neven-Spence said the Bill was not intended to deal with miscarriages, whether criminal, legal, or brought about by natural causes. Scotland, almost alone among civilized nations, did not provide for registration of stillbirths. In England stillbirths were registered and entered into the computation of the maternal mortality rate. There was therefore no true

comparison between the English and the Scottish rates. A recent report from the Committee on Health Services in Scotland made a specific recommendation for registration of stillbirths. Those in charge of public health administration in Scotland held that the information so obtained might throw light on the causes of the wastage of infant life, on maternal mortality, and on puerperal sepsis. Scotland, with some of the finest medical schools in the world, had an infantile mortality rate nearly thrice that of New Zealand, and the maternal mortality rate in Scotland showed no sign of decrease at 6 per 1,000.

Mr. BUCHANAN said he and his friends reserved the right to oppose the Bill.

Criticism of the B.M.A.'s Milk Advertisements

On March 7 Mr. GARRO-JONES asked the Minister of Agriculture whether he was aware that the expenditure of the Milk Marketing Board on advertising the merits of milk was being largely covered by an advertising campaign sponsored by the British Medical Association, in which all milk which had not been treated by certain methods was stigmatized as dangerous to health; whether he was aware that statements in these advertisements were damaging the interests of farmers producing and selling milk which, though not treated by the methods favoured by the Association, was accepted by the Ministry as of satisfactory quality; and whether he would recommend to the Milk Marketing Board an advertising policy which would neutralize the damage done to the industry by unsubstantiated statements sponsored by private interests. Mr. W. S. MORRISON said he had no information whether the advertisements referred to had had the effect ascribed to them, and he did not think that any useful purpose would be served by suggesting to the Milk Marketing Board that they should change their present advertising policy, which was designed to encourage the consumption of milk generally.

Mr. Garro-Jones said that as the Minister did not appear to appreciate the repercussions of this advertising campaign, he (Mr. Garro-Jones) would raise the matter on the motion for the adjournment of the House at the earliest opportunity.

Mr. MACQUISTEN: Will the Minister inquire who supplied the money for these costly advertisements? It is not the doctors, I presume. (An hon. member: "The distillers.")

Sickness among the Insured Population.—Sir KINGSLEY WOOD, answering Mr. Harold Macmillan on February 24, said statistics showing the incidence of sickness among women and girls in the insured population of England and Wales were not available in his Department and could be obtained only by reference to the detailed records of the 7,000 approved societies and branches which administered health insurance benefits. He was considering the question of a comprehensive investigation into the extent and incidence of various forms of incapacitating sickness among insured persons of each sex and at various ages.

Welfare Authorities and Dried Milk.—On February 24 Sir KINGSLEY WOOD said he did not know that advertisements were being sent to maternity and child welfare committees from firms manufacturing dried milk urging them to supply from firms patent products on the grounds that they could not be used for general purposes. In some instances dried milk was supplied by welfare authorities on the recommendation of their medical officer of health where this appeared desirable on medical or other grounds. The choice must be one for the discretion of the welfare authorities concerned.

Deaths from Vaccinia in 1937.—Sir KINGSLEY WOOD said on March 1 that no deaths from small-pox were registered during 1937 in England and Wales. Nine death certificates were received during the year 1937 on which death was attributed entirely or in part to vaccination, post-vaccinal encephalitis, or vaccinia. The ages of the persons concerned were respectively 3 months, 4 months (four cases), 5 months, 7 months, 14 years, and 24 years. All the deaths, except that of one child of 4 months had been assigned to the vaccinia class.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

199 Infectious Mononucleosis and Diphtheria

F. WULFF (*Ugeskr. Læge.*, January 20, 1938, p. 51) finds infectious mononucleosis to be so common and so clinically like diphtheria that some twenty to thirty cases of the former disease are admitted every year to his fever hospital in Denmark with a diagnosis of diphtheria. The importance of an early differential diagnosis is so great that the rule has now been adopted in his hospital of undertaking a leucocyte count before any diphtheria serum is given to a new case. An early leucocyte count saves the patient not only from the discomforts of serum treatment but also from prolonged hospital treatment. In a few cases of mononucleosis, the appearance of the leucocytes is not sufficiently characteristic to justify the withholding of serum, and in such doubtful cases serum should be given, as the lack of it may prove fatal in a case of genuine diphtheria. If the practitioner has not mastered the technique of the necessary blood examination he should either confide it to other hands or admit the patient to hospital for observation: he should above all remember that diphtheria is much more common than infectious mononucleosis. The clinical evidence of mononucleosis is apt to be indecisive, and even the one crucial test—the leucocyte count—may be ambiguous, for in about 2 per cent. of the cases of diphtheria in small children the behaviour of the mononuclear leucocytes is identical with that in mononucleosis.

200 Traumatic Tuberculosis

S. WIDERÖE (*Nord. med. Tidskr.*, January 15, 1938, p. 81) begins his exposure of what he calls "the legend of traumatic tuberculosis" with an account of a medico-legal case in which he had to give an expert report. The patient was a ship's captain who, between 1929 and 1934, had developed tuberculosis in four different sites, including the right knee and the left hip. Though the author admits that there is both a theoretical and experimental foundation for the conception of traumatic tuberculosis, and that up to 20 per cent. of the cases of tuberculosis of the knee have hitherto been regarded as traumatic, he maintains that this condition is a figment of the imagination copied from one textbook into another with uncritical fidelity. Trauma may, indeed, aggravate an already existing tuberculosis of a bone or joint, but if it were capable of implanting tuberculosis into hitherto non-tuberculous tissues it would assuredly have done so in one at least of about 8,000 fractures which the author has seen during twenty-five years' hospital practice. In many of these cases of fracture the patients were definitely tuberculous, yet not one of them developed tuberculosis at the site of fracture. Every year the author has treated several cases of injury to the knee with effusion of blood into the joint, but he has not seen secondary tuberculosis of the knee develop in even one of these cases. If Thiems was right in his recognition of what he called "contusion tuberculosis," justification of it ought by now to be easily found in the available clinical evidence; but such justification, in the author's opinion, is conspicuous by its absence. He has repeatedly operated on the subjects of pulmonary tuberculosis for hernia, appendicitis, and the like, but never once has he found tuberculosis develop in the track of the operation. The same is true of thoracoplastic operations for the relief of pulmonary tuberculosis. The millions of war-wounded, many of them tuberculous, in some cases at least should have demonstrated the traumatic development of tuberculosis in previously healthy tissues were the Thiems teaching correct.

Surgery

201 Fractures of the Carpal Scaphoid

O. ALEMAN (*Acta chir. scand.*, 1937, 80, 3, 217) considers that there is general agreement with regard to the treatment of recent fractures of the carpal scaphoid by prolonged immobilization, any radical operative treatment being contraindicated. On the other hand, when treatment is required for old-standing fractures or for pseudarthroses there is no unanimity as to the best treatment. Between 1916 and 1935 the author treated eighty-three patients in an army hospital in Stockholm for fractures of the scaphoid. As in two cases the lesion was bilateral and in six cases conservative treatment was subsequently supplemented by operative treatment, his "cases" totalled ninety-one, fifty-two of which concerned the right hand and thirty-nine the left. Impression fractures accounted for three cases, marginal fractures for nine, and transverse fractures and pseudarthroses for seventy-nine. During 1935 and 1936 information was obtained by examination and correspondence in about eighty-six cases. The results were found to be good in 75 per cent., not so good in 3 per cent., and bad in 22 per cent. when immobilization by plaster had been effected within three months of the fracture. The results were found to be good in 84 per cent. and less good in 16 per cent. when, with an interval of more than three months between fracture and treatment and when pseudarthroses had developed, an operation had been performed and the smaller fragment of bone had been removed. When the fragments had been of equal size the distal (radial) fragment had been removed. There were no bad results in this second group. In a third group consisting of six cases of old fractures and pseudarthroses the treatment had consisted of drilling by Beck's method followed by immobilization in plaster. The results in this group were without exception bad. The author ascribes the failures in his first group to the inadequate period of immobilization, and he now insists on immobilization for four to eleven weeks for recent transverse fractures.

202 Carcinoma of the Ampulla of Vater

W. A. COOPER (*Ann. Surg.*, December, 1937, p. 1009) describes carcinoma of the ampulla of Vater as a rare but distinct clinical entity in the group of diseases causing obstructive jaundice. This lesion is more common in men than in women, and the average age in the series of fourteen cases reviewed was 49.3 years. There was seen to be a definite relation between carcinoma of the ampulla of Vater and cholelithiasis, which was present in 22 per cent. of cases. In most instances the histogenetic origin of the tumours could not be determined, and usually the entire ampullary region was involved. Metastases are relatively uncommon, due not to any inherent benign quality of the tumour but to its location. Biliary obstruction occurs while the tumour is relatively small, and death usually takes place before there has been time for extensive growth or metastasis. Obstruction of the biliary and pancreatic ducts at the ampulla of Vater causes changes in other organs: the liver is larger than is usual in common bile duct obstruction; the head of the pancreas is often nodular and indurated; the gall-bladder and common bile duct are always dilated, and the gall-bladder may contain thick dark, or white, bile. Symptoms at the onset consist of upper abdominal or epigastric pain, followed by increasing constant obstructive jaundice, with pale stools, dark urine, and pruritus. There is rapid loss of weight, anaemia is often present, and the stools contain occult blood. The average duration of life once the diagnosis has been made is only a few months, although

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology
Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Hormones for Enlarged Prostate

Dr. S. (Bombay) writes: A physician, aged 55, is suffering from hypertrophy of the prostate. Can anyone give his experience of injections of testosterone propionate and pituitary hormones in such cases? How much of the testicular hormone should be injected, and how often? Should the pituitary hormone be given at the same time as or after the injections of testicular extract? Does this treatment obviate the need for operation?

Glycosialia?

Dr. ISOBEL G. SMITH writes: A female patient of mine, aged 70, is complaining of an almost constant sweet taste in the mouth. The condition began about a year ago, but at that time only occurred some time after a meal. The dentures which she wears become covered with a sort of sticky adherent film, in spite of washing them after eating food. The gastric juice is normal and the bowels are kept regular. A catarrhal condition of the nasopharynx was dealt with and frequent mouth washes and paints have been used, but the patient continues to complain bitterly of the disagreeable taste. I would be most interested to know if anyone can suggest a cause, and, more especially, a treatment.

Incapacitating Diarrhoea

"D. G. O." in reply to "Emdee" (*Journal*, December 11, 1937, p. 1206), writes: I suggest that "Emdee" takes one drachm of acid, hydrochlor. dil. in a wineglassful of water or lemonade, thrice daily, after meals. This very simple prescription has proved effective in a similar case of unexplained diarrhoea.

Primary Vaccination

Dr. C. LUTHER BATTESON (Watford) writes: I am in agreement with Dr. S. H. de G. Pritchard (*Journal*, March 5, p. 550) when he expresses the opinion that post-vaccinal encephalitis is largely due to the use of rabbit lymph. So far as my recollection goes these cases were not met with until some bright economist thought of using animals other than calves for the supply of lymph.

Income Tax

Employment of Maidservant

"SIGMA" asks: "What is the usual amount allowed in respect of a maid's help?" Hitherto he has been allowed £80 per annum, but the inspector of taxes wants to restrict it to £52 in future.

It is difficult to offer any general guidance because so much depends on the particular circumstances. The

amount must have regard to (a) the total cost (including board, laundry, etc.) of the domestic staff, and (b) the proportion which relates to the professional side—looking after the waiting room and surgery, attending on callers, etc. In our experience where two maids are kept an allowance of £100 per annum is not uncommon.

LETTERS, NOTES, ETC.

Human Embryos Wanted

Dr. MARY CRIPPS writes: I am doing a piece of research on human embryos, and find it very difficult to obtain specimens, especially the early ones. Those I particularly need are embryos of the sixth week of pregnancy. I would like them put in very weak formalin (2 or 3 per cent.). Readers of the *Journal* who are kind enough to send specimens of this age should address them to me at the Histology Department, Royal College of Physicians, Forest Road, Edinburgh. They must be packed in accordance with Post Office regulations.

Hydrotherapy for Rheumatoid Arthritis

"CRIPPLED" writes: With regard to the question raised by Brigadier-General F. E. Burnham as to the advisability of giving hydrotherapy in the acute stage of rheumatoid arthritis (*Journal*, February 5, p. 308), may I suggest that it is perhaps, as he has found, not hydrotherapy which should be avoided, but rather the application of heat without water. No doubt each patient reacts differently, but the following facts are from my own personal experience. In the first place, ordinary "reclining baths" with the water at a scalding temperature, in which I lay until I felt faint—that is, for about ten minutes—followed by a cold sponge, relieved pain and stiffness, but only for a few hours. Secondly, radiant heat applied to the limbs immediately produced a violent exacerbation of the symptoms. Thirdly, steam vapour baths produced a gradually cumulative damage with disastrous final results. In these baths the whole body except the head was exposed to both radiant heat and steam vapour. Finally, hot weather often increased the severity of the pain. In my own case the relief afforded by heat when applied through water was nearly as remarkable as the exacerbation of the pain when heat was applied without it.

Disclaimers

Dr. GEOFFREY KONSTAM writes: In an article in a daily newspaper on March 1 concerning an operation on a hospital patient of mine suffering from Pick's disease mention was made of my name and address. I was greatly distressed on reading this article, which was written without my knowledge or consent, and I took immediate steps to prevent a repetition of such unwanted publicity. The information was apparently given to the Press by a member of the patient's family, and I was unaware of it until the article was shown to me after publication.

Mr. FRANK J. P. O'GORMAN (Doncaster) writes: A recent article in the local Press makes reference to one of my cases in which an intracardiac injection of adrenaline was given. The report was of certain proceedings where, on behalf of others, I made a presentation to a retiring midwife. Through the courtesy of your columns I would like to disclaim any connexion with the ridiculous sensationalism of the report about this case.

Corrigenda

Drs. Jenkinson and Milne wish to draw attention to an error in their article on "Insulin-Tannic-Acid-Zinc Suspension in Treatment of Diabetes Mellitus," published in our issue of February 19. The end of the last sentence in paragraph three (page 381, sixth line of first column) should read: "with the addition of zinc, 1 milligramme to 500 units of insulin"—not "1 gramme to 500 units."

In the *Journal* of March 5 we published at page 514 an article by Dr. A. Morton Gill on "Pneumonitis." At page 517, under paragraph (f), "suffering from chorea and rheumatic carditis complicated by pneumonia," should have read, "suffering from chorea and rheumatic carditis complicated by pneumonitis."

concussion or even hard blows on the head. The reason why this sequel has hitherto largely passed unnoticed is that men dislike voluntarily confessing to impairment of their sexual activities. Indeed hardly any of the thirty-three male patients whom Professor Stier investigated referred to it of their own accord. As for its frequency, it may be noted that between writing this article and correcting the proofs thereof the author saw fifteen more cases. To recognize them it is, however, necessary to question the patient directly on the subject or to listen to what his wife has to say about it. In almost all the cases in which an aural examination was made disturbances of equilibrium were demonstrable. The chances of injuries to the head impairing the sexual activities would seem to rise with age, for all the twelve men whose sexual potency was fully retained after injury to the head were under 40 at the time. But even in these cases there was a loss of libido. Professor Stier discusses in some detail the site of the brain lesion in such cases, and he expresses doubts as to their being amenable to treatment with sex hormones or psychotherapy.

207 Traumatic Arachnoiditis

G. G. I. RADEMAKER (*Nederl. Tijdschr. Geneesk.*, January 15, 1937, p. 464), who records four illustrative cases, states that cases of traumatic arachnoiditis are often not recognized but are regarded as examples of compensation neurosis. The patients complain of headache or pains in the neck, back, or loins, which are aggravated by physical exertion and often do not develop until a year or more after the accident. There may also be sensory disturbances, changes in the reflexes, and impairment of mobility. The diagnosis can only be made after a careful examination with lipiodol.

208 Primary Melanoma of Leptomeninges

M. T. SCHNITKER and D. AYER (*J. nerv. ment. Dis.*, January, 1938, p. 45) report in detail a case of primary melanoma of the leptomeninges, and review the literature of this condition. The case at first presented the signs and symptoms of a compressive lesion at the ninth thoracic segment. A tumour with only a few granules of melanin pigment was removed at operation. Six months after operation the patient returned, complaining of vomiting, hiccoughing, blurred vision, and headaches. These symptoms progressed, and examination one month later showed that the left eye was blind with early optic atrophy, while vision in the right eye was greatly reduced, and that there was weakness of the sixth, seventh, and twelfth cranial nerves on the left side. Cerebration was poor and there was marked loss of memory. At necropsy a widespread and massive infiltration of the leptomeninges of the brain and spinal cord with tumour cells and melanin pigment was found. A small mass projecting into the third ventricle posteriorly had caused internal hydrocephalus recognized clinically by ventriculography. Neither in this case nor in any of the thirty described in the literature was the diagnosis made before death. This is in contrast to sarcomatosis of the meninges, in which the cerebrospinal fluid generally contains tumour cells. The histogenesis of melanomas of the leptomeninges is discussed.

209 Thrombophlebitis causing Hydrocephalus

C. P. SYMONDS (*Brain*, 1937, 60, 4, 531) discusses thrombophlebitis of the dural sinuses and cerebral veins as a cause of hydrocephalus and focal cerebral symptoms. The author previously described the syndrome of otitic hydrocephalus, characterized by headache, vomiting, and papilloedema in association with otitis media without abscess formation and with spontaneous recovery, as due to either excessive secretion from the choroid plexuses or defective absorption from the arachnoid villi. He now suggests that mural thrombophlebitis of the superior

longitudinal sinus may be the underlying pathological change. Evidence for this is furnished by the occurrence of cases in which hydrocephalus has been associated with proved thrombosis of the superior longitudinal sinus and also with thrombophlebitis not arising from otitis media. It is also suggested that the occurrence of focal epilepsy, or acute or subacute hemiplegia following otitis media, is most probably due to thrombophlebitis involving the superficial cerebral veins. Cases supporting this viewpoint are described. The changes in the cerebrospinal fluid in intracranial thrombophlebitis are variable. Fatal occlusion of the superior longitudinal sinus as a rule leads to the appearance of blood in the cerebrospinal fluid, but mural thrombosis in the sinus may occur with a normal cerebrospinal fluid, as has often been observed in otitic hydrocephalus. An inflammatory reaction may, however, be found.

210 Tuberculosis and Dementia Praecox

M. and A. BENVENUTI (*Lotta c. Tuberc.*, November, 1937, p. 1040) discuss the relationship between tuberculosis and dementia praecox. Such a relationship has been alleged to exist by a number of authors and denied by others, but has perhaps never previously been investigated under such favourable conditions for controlled observation. The authors were able to draw upon an unusually large mental population, since the asylum from which they drew their material houses no less than 3,800 inmates. They had no difficulty in finding fifty cases of dementia praecox, and they selected to act as controls fifty other patients whom they considered to be comparable to the praecox patients in regard to external circumstances, general hygiene, length of sojourn in asylum, duration of illness, age incidence, etc. The average age of the praecox cases was 35 and their average sojourn in the asylum eight years, as against the control group's average age of 26 and average sojourn in the asylum of nine years. Their general conclusion is that though schizophrenics may show a slightly higher incidence of tuberculosis than other asylum inmates the difference is not important enough to justify the idea of a causal nexus between the two conditions. Similarly, there would seem to be no particular form of tuberculosis more liable to occur in schizophrenics than in other mental patients, since apical, pleural, and glandular lesions were found with equal frequency in both sets of cases.

211 Physiology of Sleep

L. R. MÜLLER (*Münch. med. Wschr.*, January 21, 1938, p. 81) discusses some of the causes of insomnia. (1) Certain diseases localized in the mid-brain induce true sleeping states. They include encephalitis, narcolepsy, lesions of the posterior thalamus, and tumours of the pituitary pressing on the central aspect of the base of the brain. The existence of a sleep centre in the grey matter between the third ventricle and the Sylvian aqueduct is proven. Economo's hypothesis of a dual nature of this centre, one promoting waking, the other sleep, is probably correct. (2) Cerebral anaemia, hyperaemia, or haemorrhages into the brain do not produce sleep states in the strict sense but only loss of consciousness. Various agents induce sleep by a general action on the central nervous system, not on the sleep centre. They include alcohol, hypnotics, bacterial toxins, and infections of the brain. The assumption of hypnotoxins which poison the brain as a result of physiological metabolic processes being the factors inducing sleep has much to be said for it, but has not been proved. (3) Psychological disturbances, pain, and mental disease may all cause insomnia. Müller believes that the induction of the sleeping or waking state can be explained on the basis of the ion fluctuations in the body. In sleep potassium and calcium ions wander from the serum into the neuromuscular apparatus; the sodium ions move from the liver into the mucous membranes. Potential energy is stored during sleep. In the

some cases have lived for three years or more. Operative treatment, which is often delayed by the poor condition of the patient, is rarely more than palliative, as by cholecystostomy or cholecystogastrostomy. In any case it should aim first at the relief of the biliary obstruction, secondly at the removal of its cause by transduodenal resection or by radical resection of the duodenum and head of the pancreas. A two-stage operation is fully described which has been devised for use in cases in which the tumour is ulcerating and infiltrates the duodenal wall.

Therapeutics

203

Oleo thorax

F. RAVAZZONI and G. CROCE (*Riv. Patol. Clin. Tuberc.*, December 31, 1937, p. 951) discuss the question of the prevention of exudates after the induction of an artificial pneumothorax. They begin by surveying the effects, good and bad, of pleural effusion in these cases, and come to the conclusion that the bad outweigh the good. Accordingly they set out to try to prevent the development of effusions by Unverricht's method of injecting 1 or 2 c.cm. of sterile olive oil into the pleural cavity at one of the early refills, the theory being that the minimal trauma thus produced gives rise to a degree of fibrosis sufficient to act as a barrier against the spread of infection and increase the natural or spontaneous defensive powers of the pleura. They treated seventy-two patients by this method. The proportion of patients with no effusion at the end of one year was 67 per cent., which, as they point out, is fairly high. The injections were well borne by most of the patients; as Unverricht also noted, they complain of some pain and slight dyspnoea and there is also some pyrexia during the first twenty-four hours after the injection, and there is a slight basal effusion which persists for a few days after the disappearance of the other symptoms. The authors state that refills after the introduction of the oil should be kept at a low tension for some time, so as to avoid a double stimulus to the pleura. As a result of their investigations the authors conclude that in addition to being harmless Unverricht's method is definitely useful in reducing the occurrence of effusions after the induction of artificial pneumothorax.

204

Pernicious Anaemia

E. MEULENGRACHT (*Med. Welt*, January 22, 1938, p. 132) discusses the theory of the treatment of pernicious anaemia in the light of present-day knowledge. He begins by restating his belief in Castle's well-known three-factor theory involving (1) an intrinsic factor in the stomach, (2) an extrinsic factor in the food, and (3) a liver factor (usually referred to as the P.A. factor) formed by the interaction of (1) and (2), absorbed from the intestine and stored chiefly in the liver. This factor is relatively thermostable, and would appear to be a fairly simple compound with a relatively small molecule. It has not yet been chemically identified. The extrinsic factor is thermostable and occurs in a variety of substances all containing the vitamin B complex. The intrinsic factor is thermolabile, and seems to be of the nature of an enzyme, since it is not active by itself but only becomes so in the presence of the extrinsic factor. Meulengracht has studied the comparative histology of the porcine and the human stomach. In both the intrinsic factor is believed to be produced by the pyloric gland cells, but the area of these glands is much more restricted in man than in the pig. Curiously enough, these cells do not appear to be greatly affected in pernicious anaemia, but Meulengracht does not consider that this evidence is sufficient to invalidate the theory that the anti-anaemic factor is produced by these pyloric glands. He thinks

that quantitative investigations may afford an explanation of this apparent paradox. Regarding the treatment of pernicious anaemia, Meulengracht states that this may be based either on the liver factor or on the other two factors—that is, it may be administered in the form of liver extract, pylorus-gland powder, or some form of food containing the extrinsic factor. He deprecates the present-day vogue for parenteral liver therapy, and thinks this method should be reserved for emergencies. He believes that the future lies with some form of combination therapy, either by giving preparations in which the mucosa of the pig's stomach has been allowed to act on liver substance and then dried into a powder or by mixing pylorus-gland powder with a liver preparation and water immediately before administration, as he has himself been doing for the last two years. This has the advantage that much smaller quantities can be given, since the effect is increased by potentiation, so that it is much greater than the sum of the ingredients of the mixture. Moreover, the liver residue left over from the preparation of liver extract may be utilized in this way instead of being thrown away.

Neurology

205

Surgery of Facial Neuralgia

D. PETIT-DUTAILLIS (*Progr. méd.*, Paris, January 15, 1938, p. 82) emphasizes the good prognosis which follows the surgical treatment of facial neuralgia. The mortality is practically nil in the hands of a skilled surgeon. Injections of alcohol into the infra-orbital canal give only temporary relief and may be followed by the appearance of haematomata or by oculomotor paralysis, while injections round the nerve trunks where they emerge from the skull may cause trismus, temporo-maxillary ankylosis, or necrosis of the superior maxilla. The injection of alcohol around the Gasserian ganglion gives a satisfactory result, but is accompanied by the risk of keratitis. To avoid these complications electrocoagulation of the ganglion has been tried, but the results are still too recent for the efficacy of this method of treatment to be judged. Various forms of operative treatment have been tried, and one which has proved satisfactory is the division of the root behind the ganglion—retro-Gasserian neurotomy. This is carried out by trephining through the temporal fossa. It is suggested that in some cases it may not be advisable to cut right across the root in order to prevent recurrence, but partial neurotomy is only applicable to those cases in which the site of the neuralgia is localized to one of the two inferior branches and is not suitable for ophthalmic neuralgia. Neurotomy by the temporal route is a comparatively safe operation, the mortality being low. In forty-one cases so treated there were only two deaths due to the operation, and there were no instances of post-operative facial or oculomotor paralysis. Thirty-eight per cent. of cases developed keratitis following total neurotomy, and only 10 per cent. after partial neurotomy. This procedure is recommended for old people, for fat persons with short necks, and in cases in which treatment has been delayed or recurrence is feared. The posterior route is indicated in the case of young persons in good physical condition, when a sympathetic neuralgia is suspected, or when complete section of the nerve is necessary. Operation by this method offers the least danger of keratitis.

206

Head Injuries and Sexual Activities

E. STIER (*Dtsch. med. Wschr.*, January 28, 1938, p. 145) has found that in a high proportion of cases of injury to the head the sexual activities are more or less seriously impaired. This is so not only with fractures of the skull and severe concussion of the brain but also with slight

MENFORMON TABLETS

to reverse
menopausal changes

" Finally there is one important observation that I would bring to your notice : Patients treated with œstrin, for whatever complaint, frequently volunteer the information that they experience a sense of well-being. All of us suffer only too frequently from the voluble and discontented menopausal patient, with all her aches and pains, and I have been gratified by the CHANGE OF MENTAL ATTITUDE which œstrin has afforded to some of the patients, converting them almost into cheerful kindly rays of sunshine."

waking state it is discharged and the positive ions go back into the blood serum. A sudden fall in the electrical potential has been noted in Addison's disease and infectious conditions characterized by insomnia. The difference in the need of sleep in different persons may be explained on the grounds of greater or lesser rapidity of exchange of ions or in the intensity of exchange. In old age the electrical potential sinks. Insomnia in the aged may be regarded as a physiological process.

212 Neuromyelitis Optica

- M. GOZZANO (*Riv. Neurol.*, December, 1937, p. 530) describes a case of neuromyelitis optica (so-called Devic's disease), of which some 130 cases, with forty-nine necropsies, have been described since 1894; his patient died within three months. Both clinical and histological findings were typical. The former consisted in acute flaccid paraplegia from transverse myelitis, shortly followed by blindness from bilateral retrobulbar neuritis with initially normal ophthalmoscopic findings, the latter in intrachordal necrosis affecting chiefly the myelin sheaths but also axis cylinders and neuroglia (with no proliferative changes in the latter), with similar changes in the optic nerve from chiasma to bulbus oculi. The histological changes, although most marked at the seventh dorsal segment, extended throughout the cord; their distribution suggested a passage of the unknown virus along the central canal, and was not perivascular. Gozzano regards neuromyelitis optica as differing from all other diffuse and disseminated non-suppurative morbid conditions of the brain and cord. From disseminated sclerosis, of which it has been said to be a special manifestation, it is distinguished histologically (although clinical confusion is possible in old, stationary cases of Devic's disease and in disseminated sclerosis which began acutely) by the distribution of the lesions and their non-sclerotic nature. It is also to be distinguished from Schilder's disease (periaxial encephalitis), in which although demyelination is prominent neurological proliferation is present, and although blindness accompanies paraplegia amentia follows. The occasional occurrence of transitional forms, in which necrotic changes coexist with sclerotic plaques, cannot, however, be denied.

Obstetrics and Gynaecology

213 Follicular Hormone Treatment of Sterility

C. REICHELT (*Med. Klinik*, January 21, 1938, p. 82) in the treatment of primary sterility advises the daily administration in tablet form of 1,000 mouse units of folliculin from the first to the twenty-first day of the menstrual cycle; if this is unsuccessful after six months fifteen injections of 10,000 units should be given twice weekly. Additional measures are the exhibition of vitamins E and D, and hydrotherapeutic treatment to improve the blood supply of the pelvic organs. Three successful instances of the injection therapy are described, the patients having been married five, seven, and fourteen years respectively. The preliminary investigations which should precede such a treatment include examination of the husband, search for organic disease in the uterus, vagina, and adnexa, and tubal inflation; little is to be expected from the correction of abnormal positions of the uterus—they are often an expression of genital infantilism, for which hormone treatment is well adapted.

214 Caesarean Section for Extensive Venous Thrombosis

F. ISBRUCH (*Zbl. Gynäk.*, January 8, 1938, p. 83) would add extensive venous thrombosis, especially when affecting the pelvic veins, to the indications for Caesarean section. In his own case of bilateral saphenous thrombosis extending on one side into the pelvis he believes that vaginal delivery would have brought the risk of

tearing the oedematous parts, or of embolic detachment during the increase of blood pressure accompanying the pains or from pressure of the descending part on the large venous trunks. The rarity of reports of extensive thrombosis at term and during labour is possibly due; as Sahler suggests, to such cases being recognized only at necropsy or not at all. Six cases of lethal embolus during or just after labour in those with venous thrombosis are mentioned; in two Caesarean section was done, but after thirty hours' labour in one and after the embolism had occurred in the other. In the author's case and four others early Caesarean section was successful. Isbruch believes that the undetected consequences of thrombosis explain many obscure cases of sudden death associated with labour.

Pathology

215 Transmissible Myeloid Leukaemia in Mice

E. STORTE (*Rif. med.*, December 4, 1937, p. 1731) records his observations on a series of 120 white mice infected with a strain of myeloid leukaemia recently isolated by Furth. In dealing with the relations between acute and chronic leukaemia he emphasizes the importance attaching to consanguineous factors and the route of inoculation in experimental leukaemia. He shows that in animals as in man there exist both chronic and acute forms of the leukaemic process, differing profoundly from one another in their manifestations, but that both these forms of leukaemia are produced by the same aetiological agent and therefore are merely two expressions of the same disease. The demonstration that in the animal the acute leukaemic form, which is in every way comparable with the human form, is obtained without the intervention of microbial agents or filterable viruses proves that the factors concerned are not so much exogenous as conditions closely inherent in the individual and of a completely unknown character. From every point of view the resemblances between the transmissible myeloid leukaemia in mice and human myeloid leukaemia cannot be more numerous or complete. In conclusion Storte maintains that the affection can only be produced by living cells, and arises by multiplication of the inoculated leukaemic elements. On subcutaneous inoculation of the blood or any material containing the living leukaemic cells a tumour arises, while on intravenous injection of the same material typical leukaemia is produced. The bone marrow is the tissue which is always affected first by the leukaemic process, and in a more intense degree than any other organ. The extramedullary leukaemic tissue, such as that which infiltrates the liver, spleen, etc., does not have an autochthonous origin, but originates from leukaemic elements in the bone marrow. Finally Storte maintains that the transmissible myeloid leukaemia of the mouse shows the fundamental characteristics of a neoplastic growth, or at least of an affection in every way identical with the typical transmissible neoplasms of mammals.

216 Allergic Skin Reactions in Undulant Fever

G. ANDREI and F. BUA (*Minerva med.*, December 23, 1937, p. 684) have found that a suspension of *Br. abortus* produces more intense and lasting positive reactions, which are easier to interpret and can be more clearly distinguished from the slight reactions sometimes found in persons who are not infected but presumably have been rendered allergic by having swallowed food containing bacterial antigens, than does Burnet's test. They therefore employ 0.1 c.cm. of a stock vaccine which in positive cases gives rise to reactions lasting more than four days, while with higher doses the reactions may persist for as long as thirty days. In 100 controls the test was negative with one exception.

DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

Uralysol, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

Efficient and Effective Support

SCIENTIFICALLY Applied

The secret of the success of the Curtis Abdominal Support No. 1 lies in its scientific application of power. At all times it gives even anterior-posterior pressure without undue constriction of the lower abdomen. The resulting support obtained allows for greater freedom and comfort than ever before. Medical men prescribe the Curtis Model No. 1 for all forms of abdominal ptosis, viscerop-tosis, enterop-tosis and gastrop-tosis, and it is also recommended for support of ventral hernia and scar tissue in the lower abdomen.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Blaud. The iron-content remains fresh and unoxidized indefinitely, and

injury to teeth is avoided.

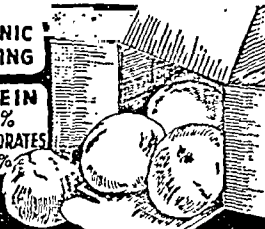

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

Tel.: 64117. For terms, etc., apply to the Medical Superintendent.

Telephone: Rodney 2611-2612.

The above House, which was established in 1826, is an Institution for the care and treatment of persons suffering from mental diseases and nervous disorders. Certified voluntary and temporary patients are received. Separate houses for treatment and accommodation of special cases adjoin the Institution. There is a seaside branch, Kearney Court, near Dover, to which patients may be sent for treatment or on holiday. Motor and carriage exercise is provided as required. Patients can avail themselves of a course of physical drill. Tennis courts. Entertainments, dances, and indoor amusements held throughout the year. Terms from £3 3s. per week. Illustrated prospectus and further particulars can be obtained from the Medical Superintendent.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL

MARYLEBONE ROAD, N.W.1

Medical Students and Qualified Practitioners admitted to the Practice of this Hospital. Unusual opportunities are afforded of seeing Obstetrical Complications and Operative Midwifery (about one half of the total admission being primiparous cases). Over 2,000 patients are admitted to the Wards annually, and in the Ante-natal department there are over 20,000 attendances per annum. Clinical demonstrations are given by the Staff daily.

For rules, fees, etc., apply H. B. STOKES, Secretary-Superintendent.

CITY OF LONDON MATERNITY HOSPITAL

(Incorporated by Royal Charter)

CITY ROAD, E.C.1.

The Hospital offers facilities to POSTGRADUATES for observing the work of its Antenatal, Postnatal and Dental Clinics; and to male MEDICAL STUDENTS (and Practitioners desiring a Refresher Course) a two or four weeks' Midwifery Course (Residential). Nearly 2,000 patients annually.

RALPH B. CANNINGS, Secretary.

THE ROYAL SOCIETY

MOSELEY RESEARCH STUDENTSHIP.

Applications are invited by the Council of the Royal Society for a MOSELEY RESEARCH STUDENTSHIP of the value of £350 per annum, awarded for "the furtherance of experimental research in pathology, physics and chemistry, or other branches of science, but not in pure mathematics, astronomy, or any branch of science which aims merely at describing, cataloguing, or systematizing."

Preference will be given on this occasion to applications with reference to research in a biological subject, having some bearing on the problems of pathology.

Applicants should give the names of two referees. Testimonials will not be considered. The subject of the proposed research and the place at which it would be carried out should be given.

The appointment will be for two years in the first instance and may in exceptional cases be renewed from year to year up to a maximum of five years in all.

Applications should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W.1, and should be received as early as possible, in any case not later than May 1st, 1938.

February, 1938

Any Member of the Medical Profession admitted on presentation of card.

By Order of the President.

H. M. BARLOW, Secretary.

Budapest Spa

The distinguished record of successful cures effected in Hungary's delightful capital indicates in some slight measure the remarkable healing powers of its natural water springs.

All told there are more than 80 sulphur and radio-active thermal springs (96° F. to 162° F) in addition to over 200 aperient water springs. These, it is calculated, produce 11 million gallons of curative waters daily.

Unsurpassed in comfort and efficiency, the modern Spa establishments remedy many kinds of disorders, particularly of Rheumatic Diseases, Sciatica, Arthritis, Fibrositis, Diseases of Women, Chronic Skin Disorders, etc.

As additional incentives to the visitor, Budapest offers all the amenities and attractions of a large metropolis, amid the glorious surroundings that have made Hungary famous the world over.

Three weeks' treatment in Budapest, including accommodation at Spa Hotel, sight-seeing, tips, taxes, and second-class ticket from London, costs only **£32:15:0**

INDIAN MEDICAL SERVICE

RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or of £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 32 years of age and who are registered under the Medical Acts in force in Great Britain and Northern Ireland are eligible to apply.

CAREERS.

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, specialist and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

RATES OF PAY.

Years of Service	Rank	Basic Pay Rs. per mensem	Over-seas Pay £ per month	Total £ per annum
1	Lieutenant	450	15	585
2	Captain	500	25	750
3	"	550	25	775
4	"	550	25	775
5	"	600	25	825

23	"	1350	40	1695
24	"	1500	40	1830
25	"	1500	40	1830

Note.—(1) The rupee is at present stabilized at a rate equivalent to 1s. 6d.

(2) An officer promoted to the rank of Lieut.-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1250 per mensem (basic) plus £40 per month overseas pay.

Extras.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized

hospitals may be seconded in those posts for a period. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to 18 months.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed twelve months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America and Canada, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pensions are as follows.— Per annum.

After 17 years' service for pension	Per annum.
.. 18	£372 Os.
.. 19	£400 Os.
.. 20	£428 Os.
.. 21	£465 Os.
.. 22	£502 Os.
.. 23	£539 10s.
.. 24	£576 10s.
.. 25	£614 Os.
.. 26	£651 Os.
.. 27	£697 10s.
.. 28	£744 Os.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at Royal Army Medical College and at Aldershot, lasting approximately three months, prior to their embarkation on first appointment. Information as to the rates of pay during this period and subsequently up to the date of embarkation is contained in the memorandum referred to.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the OFFICE OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W.1. Office early in April next, and the selected candidates, unless seconded for hospital appointments, will be required to report to the India Office for instruction commencing about 1st May, prior to sailing for India in September, as soon as possible.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK STREET, LONDON, W.1.
Tel.: Welbeck 8901.

PROVIDES HIGHLY SUCCESSFUL
ORAL AND POSTAL COACHING FOR
ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S. ENGLAND. M.C. CANTAB.
(Primary & Final.) M.S. LONDON.
F.R.C.S. EDINBURGH.

And all other Surgical Degrees and Diplomas.

- 1 The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
- 2 Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.
- 3 The Surgical Tutors of the College all hold either the M.S. Lond. or F.R.C.S. England, or both, and are highly experienced teachers.
- 4 The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S." free on application to the Secretary.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

A VACANCY exists for an ASSISTANT PATHOLOGIST in the MALAYAN MEDICAL SERVICE.

Candidates must be British subjects of European parentage, between 25 and 35 years of age, and must possess medical qualifications registrable in the United Kingdom, and have had at least six months' experience of post-graduate work in a recognised hospital or clinical laboratory.

Appointment is on probation for three years in the first instance, with a salary of £700 a year rising annually by £35 to £770. Thereafter, subject to satisfactory service, the officer may be placed on the permanent pensionable establishment with salary of £805 a year rising by annual increments of £35 to £1,120 a year. Private practice is not allowed.

DUTIES. The selected candidate will be required to perform such bacteriological and pathological work of the Government Institutions in Malaya as may be directed by the Director/Adviser, Medical Services, and possibly to give lectures at the King Edward VII College of Medicine, Singapore, and teaching institutions.

FREE PASSAGES provided for the officer and his family, not exceeding five persons in all.

QUARTERS. Furnished quarters provided, if available at a rent of 6% of salary.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S.W.1. Completed applications must be received by March 21st.

UNIVERSITY OF DURHAM.

KING'S COLLEGE, NEWCASTLE-UPON-TYNE.

Applications are invited for the whole-time post of ASSISTANT BACTERIOLOGIST in the Public Health Laboratory in the Medical School. Applicants must be registered Medical Practitioners with some experience of practical Bacteriology. Preference will be given to holders of a Diploma in Public Health.

Salary £350 to £450, according to experience.

Full particulars may be obtained from the Secretary to the Council, King's College, Newcastle-upon-Tyne, 2, to whom seven copies of applications, stating experience, with seven copies of three recent testimonials, should be submitted not later than Saturday, March 20th, 1938.

UNIVERSITY OF LONDON

The Senate invites APPLICATIONS for GRANTS for specific projects of research to cover approved expenses, and for the provision of materials and apparatus not otherwise available. Applicants must be members of the University of London or teachers in a School of the University. Forms of application (which should be returned by March 1st, 1938) and Regulations may be obtained from the Academic Registrar, The Senate House, University of London, W.C.1.
March, 1938.

Salary £200 per annum, plus maintenance. Applications, stating age, qualifications, experience, etc., together with copies of three recent testimonials, should reach the undersigned not later than Thursday, March 17th, 1938.

Memorial Offices, D. A. POWELL,
Westgate Street, Principal Medical Officer
Cardiff. March 7th, 1938.

BRITISH POSTGRADUATE MEDICAL SCHOOL.

Applications are invited for the post of ASSISTANT (non-resident) in the Department of SURGERY at the above-named School. Candidates should hold a higher qualification in Surgery. The post will normally be at a salary of £250-£500, according to experience and qualifications. Further particulars can be obtained from the Dean of the School, Dr. J. Shepherd, 2, W.12, to whom applications should be accompanied by two testimonials and a list of names of two referees, should be submitted not later than the first post on March 25th, 1938.

COUNTY COUNCIL OF MIDDLESEX. APPOINTMENT OF OBSTETRIC SURGEONS.

Applications are invited from registered Medical Practitioners for the following appointments on the permanent staff. The appointments are senior ones in the Council's general hospital service, and applicants are expected to be medical men or women of high qualifications and professional attainments who have devoted their time wholly or chiefly to the practice of obstetrics and gynaecology. The successful candidates will work under the direction of the Medical Superintendent of the respective hospitals, and the whole of their time must be given to their official duties. They must be prepared to undertake the teaching of students, if required, and to carry out such other duties as the County Council may from time to time direct.

REDHILL COUNTY HOSPITAL,
Edgware.

SENIOR OBSTETRIC SURGEON.

Salary £850 per annum, rising by annual increments of £50 to £1,350 per annum, together with a non-resident cash allowance of £150 per annum in lieu of emoluments.

NORTH MIDDLESEX COUNTY HOSPITAL,
Silver Street, Edmonton, N.18.

OBSTETRIC SURGEON.

Salary £700 per annum, rising by annual increments of £50 to £750 per annum, and after five years' service, by two further increments of £50 to £850 per annum, together with a non-resident cash allowance of £150 per annum in lieu of emoluments.

The successful candidates will be required to reside within a short distance of the hospitals to which they are appointed. In the case of an unmarried officer, if accommodation is available, full residential emoluments may be provided in lieu of the non-resident allowance.

The above salaries are inclusive, and any fees received by the officers appointed must be paid over to the County Council.

The appointments will be subject to medical examination, will be held during the pleasure of the Council, and are terminable by three months' notice on either side.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 15th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Obstetric Surgeon."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z."

Clerk of the County Council.

Middlesex Guildhall,

Westminster, S.W.1.

February 26th, 1938.

AMENDED ADVERTISEMENT.

BOROUGH OF EALING.

ASSISTANT MEDICAL OFFICER

Applications are invited from fully qualified Medical Men (single) with a Public Health qualification for the position of Assistant Medical Officer.

A candidate must have had experience in the treatment of cases of infectious disease at an Isolation Hospital. The duties will include the medical care of patients in the Chiswick and Ealing Isolation Hospital, South Ealing, and the medical inspection and treatment of school-children at schools and health centres in the Borough of Ealing.

The person appointed will reside at the Isolation Hospital where furnished rooms and board will be provided.

He will be required to devote his whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £450 per annum, rising by £25 per annum to a maximum of £550, plus board and residence, as indicated above and valued at £150 per annum.

A deduction of 5 per cent will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application forms and terms of appointment can be obtained from Dr. Thomas Orr, Medical Officer of Health, Town Hall, Ealing, W.5, to whom application, accompanied by copies of not more than three recent testimonials, must be delivered not later than March 17th.

H. WANKLYN,

Town Hall, Ealing, W.5.

Town Clerk.

COUNTY COUNCIL OF MIDDLESEX. PHYSICIAN

Applications are invited from registered medical practitioners for the permanent appointment of a Physician to the COUNTY SANATORIUM, HAREFIELD. Applicants are expected to hold high qualifications, and to have devoted themselves wholly or chiefly to the practice of clinical medicine with special experience in the treatment of pulmonary tuberculosis.

The successful candidate will work under the direction of the Medical Superintendent, and the whole of his time must be given to his official duties. He must be prepared to act as consultant to general medical practitioners outside the sanatorium if called upon to do so, to undertake the teaching of post-graduate students if required, and to carry out such other duties as the Council may from time to time direct.

The appointment is non-resident, and the successful candidate will be required to reside within a short distance of the sanatorium. The appointment, which will be subject to medical examination, will be held during the pleasure of the Council, and is terminable by three months' notice on either side.

Salary £1,600 per annum (including living-out allowance of £150 per annum), rising by annual increments of £50 to £1,650. The salary is inclusive, and any fees received by the officer appointed must be paid over to the Council.

The Harefield County Sanatorium, which accommodates 378 patients (men, women and children), has just been completely rebuilt and embodies many new features in hospital construction.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 15th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Physician, Harefield County Sanatorium."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z."

Clerk of the County Council.

Middlesex Guildhall,

Westminster, S.W.1.

February 26th, 1938.

GLOUCESTERSHIRE COUNTY COUNCIL.

TWO ASSISTANT COUNTY MEDICAL OFFICERS OF HEALTH.

Gloucestershire County Council invite applications for the appointments of Two Assistant County Medical Officers of Health.

The salary in each case will be on the scale £500 p.a. to £700 p.a., and the local government service will be counted in assessing the commencing salary. Travelling and subsistence allowances will be paid in accordance with the Council's scale.

The posts are designated for the purposes of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidates will be required to pass a medical examination by the Council's medical adviser. Applicants must be registered Medical Practitioners and should hold a Diploma in Public Health. Previous experience in various branches of public health and school medical work is desirable.

Forms of application, with particulars of the duties and conditions of appointment, may be obtained from the County Medical Officer of Health, Shire Hall, Gloucester, to whom completed applications, with copies of three recent testimonials, should be sent not later than March 24th, 1938.

Canvassing, directly or indirectly, will disqualify.

RICHARD L. MOON,

Clerk of the County Council.

Shire Hall, Gloucester.

COUNTY BOROUGH OF WEST BROMWICH. HALLAM HOSPITAL (472 Beds).

HOUSE SURGEON.

Applications are invited from fully qualified male registered practitioners for the above-mentioned post. The appointment is for six months, with eligibility for a further six months. Either party may give six weeks' notice terminating the appointment. There is a visiting staff of eight physicians and surgeons, one resident surgical officer, and three resident medical officers.

Salary £200 per annum, with board-residence. All fees received by the person appointed will be payable into the funds of the Council.

Applications, stating age, experience and qualifications, together with copies of three recent testimonials, must be forwarded to the Medical Officer of Health, 2, Lodge Road, West Bromwich, so as to arrive not later than by first post on Wednesday, March 16th, 1938.

Town Hall,

West Bromwich.

March 3rd, 1938.

G. F. DARLOW,

Town Clerk.

COUNTY COUNCIL OF MIDDLESEX. ANAESTHETIST.

WEST MIDDLESEX COUNTY HOSPITAL,
Isleworth.

Applications are invited from registered Medical Practitioners for the above appointment. Candidates must have held resident appointments in a general hospital, and must be specially skilled and experienced in the administration of anaesthetics by modern methods. The officer appointed will be required to administer anaesthetics, and to carry out such other duties as may be allotted to him.

Salary £400 per annum, rising by annual increments of £25 to £475 per annum. The successful candidate will be required to reside within a short distance of the hospital, and will be paid a cash allowance of £100 per annum in lieu of residential emoluments.

The appointment (which will be subject to medical examination) will be held during the pleasure of the Council, and will be terminable by one month's notice on either side) is for a period of four years, the last year of which period the officer will leave the Council's service. In special cases the Council may decide to retain an officer on the established staff, in which case the salary will be increased to £500 per annum, which will be the maximum for a non-resident officer in this grade.

The officer appointed will work under the control of the Medical Superintendent, will devote the whole of his time to official duties, and will have no rights under the Council's superannuation scheme.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 15th. Relationship to any member or officer of the Council must be disclosed in the application. Application forms are not provided. Envelopes must be endorsed "Resident Anaesthetist, West Middlesex County Hospital."

Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z."

Clerk of the County Council.

Middlesex Guildhall,

Westminster, S.W.1.

February 26th, 1938.

N.B.—The West Middlesex County Hospital is a General Hospital with accommodation for approximately 500 acute and 600 non-acute cases.

COUNTY COUNCIL OF MIDDLESEX.

NORTH MIDDLESEX COUNTY HOSPITAL,
Edmonton.

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER

Applications are invited for the above appointment. Candidates must be registered Medical Practitioners who have held a resident appointment in a General Hospital. The duties of the appointment will be mainly obstetrical and gynaecological. Salary £250 per annum, with board, laundry and laundry, valued at £100 per annum.

The officer appointed will work under the direction of the Medical Superintendent, and will devote his or her whole time to official duties.

The appointment (which does not at present carry any superannuation rights, will be subject to medical examination, and is terminable by one month's notice on either side) is for a period of six months in the first instance, and may be extended for an additional six months.

Applications, stating age, qualifications and experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than March 15th. Relationship to any member or officer of the Council must be disclosed in the application.

Application forms are not provided. Envelopes must be endorsed "Junior Assistant Medical Officer, North Middlesex County Hospital." Canvassing, directly or indirectly, will be a disqualification.

C. W. RADCLIFFE, "Z."

Clerk of the County Council.

Middlesex Guildhall,

Westminster, S.W.1.

February 23rd, 1938.

ROCHDALE INFIRMARY AND DISPENSARY. (110 Beds. Three Residents.)

The Board of Management invites applications for the appointment of HOUSE PHYSICIAN (Male). The salary attached to the appointment is at the rate of £150 per annum, with board, residence, laundry. The duties include work in the Out-patient, Aural, Ophthalmic, etc. Departments, as well as in the wards. The Hospital covers a large industrial area and affords excellent opportunity for experience.

Applications, stating age, nationality, etc., with three recent testimonials, to be sent to the Secretary, Rochdale Infirmary.

Infirmary Office.

Rochdale.

W. WYNNE,

Secretary.

MEDICAL RESEARCH COUNCIL**KATHLEEN SCHLESINGER RESEARCH FELLOWSHIP.**

The Medical Research Council invite applications for the **KATHLEEN SCHLESINGER RESEARCH FELLOWSHIP**. This Fellowship is provided from a fund established by the late Mr. Eugen M. Schlesinger and Mrs. Schlesinger in memory of their daughter. It will be awarded by the Council, under the terms of the Trust Deed, to a suitably qualified person who will devote his or her whole time "to investigating the origin and nature of cysts of the brain, whether arising from tumours or not, or to such studies of other conditions of the central nervous system as the Council may from time to time permit." It will ordinarily be tenable at the National Hospital for Diseases of the Nervous System, Queen Square, London, and for a period of one year in the first instance. The stipend will be at the rate of £300 per annum, with up to £50 per annum for research expenses. Applications, stating age, qualifications and research experience, together with the names of two referees, should be lodged with the Secretary, Medical Research Council, 38, Old Queen Street, Westminster, S.W.1, before March 31st, 1938.

BARBADOS

The Secretary of State for the Colonies has been requested by the Governor of Barbados to assist the Board of Directors of the **BARBADOS GENERAL HOSPITAL** in the selection of a **MEDICAL SUPERINTENDENT** for the Hospital.

Candidates must be British subjects of European parentage, hold medical qualifications registrable in the United Kingdom, and have had practical experience of hospital administration. The selected candidate will be responsible to the Hospital Board for the general administration, discipline, and working of the Hospital, which has 243 beds.

SALARY. £700 a year rising by annual increments of £20 to £800 a year.

QUARTERS. Free furnished quarters will be provided with free water and an allowance for lighting.

PASSAGES. Free first class transport will be provided.

The appointment will be for a period of five years.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 8, Buckingham Gate, London, S.W.1. Completed applications must be received not later than March 31st.

APPLICATIONS FOR MEDICAL PRACTITIONER.

Applications are invited by the **DISTRICT COUNCIL OF KAROONDA, SOUTH AUSTRALIA**, from duly qualified medical practitioners, who are members of the British Medical Association, for private practice in Karoonda and surrounding district, under a guarantee by the Council of £800 per annum.

Applications, stating age and qualifications, and accompanied by copies of credentials, should be in the hands of the Agent General and Trade Commissioner for South Australia, British Industries House, Marble Arch, London, W.1 (from whom further particulars can be obtained), by March 29th, 1938.

By Order of the Council,
Karoonda, E. R. MIELL, District Clerk
South Australia.
January, 1938.

CITY OF BIRMINGHAM. SELLY OAK HOSPITAL. (520 Beds.)**RESIDENT PHYSICIAN.**

Applications are invited for the above whole-time appointment from fully qualified registered medical practitioners who have had good medical experience, and who should hold the degree of Doctor of Medicine of one of the Universities of the United Kingdom, or who should be members of the Royal College of Physicians of London.

Furnished quarters, rations, laundry and attendance will be provided, or alternatively a cash allowance will be paid if the officer appointed should be non-resident.

Salary will be £650, rising by annual increments of £50 to a maximum of £900 per annum, together with the emoluments stated above.

The appointment will be dependent on the candidate passing a medical examination, and be subject to the Birmingham Corporation's Superannuation Scheme and the Birmingham Municipal Officers' Widows' and Orphans' Pensions Scheme (if applicable). The appointment will be terminable by one month's notice on either side.

Further particulars of the appointment may be obtained from the Medical Superintendent of the Hospital.

Applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, and endorsed "Physician," should be sent to the Medical Superintendent not later than Wednesday, March 23rd, 1938.

The Council House, F. H. C. WILTSHIRE, Birmingham. Town Clerk.

WARWICKSHIRE COUNTY COUNCIL.**DEPUTY COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.**

Applications are invited from registered medical practitioners not over 45 years of age holding the Diploma of Public Health for the post of **DEPUTY COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER**. Previous administrative experience will be considered an advantage.

The salary is at the rate of £750 per annum, rising by annual increments of £50 to a maximum of £850 per annum, and is subject to a deduction of 5 per cent. in respect of contributions under the Local Government and Other Officers' Superannuation Act, 1922.

The person appointed will be required to use his own motor car in the service of the Council and will be paid in respect of such use a mileage allowance in accordance with the Council's scale from time to time in force. Subsistence allowances according to scale will also be paid.

The appointment is subject to the production of a medical certificate in a form satisfactory to the County Medical Officer of Health. Forms of application and statement of the duties and terms of appointment can be obtained from the County Medical Officer of Health, Shire Hall, Warwick, to whom applications, with copies of not more than three recent testimonials should be sent not later than Monday, March 28th, 1938.

Canvassing, directly or indirectly, will be a disqualification.

L. EDGAR STEPHENS,
Shire Hall, Warwick. Clerk of the Council.
February 28th 1938.

NORFOLK COUNTY COUNCIL.**ASSISTANT COUNTY MEDICAL OFFICER.**

Applications are invited from medical practitioners holding a diploma in public health or similar qualification.

The salary will be £600 per annum rising, on satisfactory service, by yearly increments of £25 to £700, with travelling expenses in accordance with the Council's scale. The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the salary will be subject to the statutory deduction for this purpose. The successful applicant will be required to pass a medical examination.

The Officer appointed will act under the County Medical Officer as Medical Officer to the County Isolation Hospital (non-resident), as Assistant School Medical Officer for a small area, Medical Officer to Infant Welfare Centres, and will be required to perform such other duties as may be assigned to him. He will be required to reside at East Dereham.

The appointment will be subject to three months' notice by either side.

Applications must be made on the prescribed form, which can be obtained from the County Medical Officer, Public Health Department, 29, Thorpe Road, Norwich, to whom they should be returned, accompanied by copies of three recent testimonials, not later than March 19th, 1938.

H. C. DAVIES,
County Offices, Clerk of the County Council.
Thorpe Road, Norwich.

NORFOLK COUNTY COUNCIL.**APPOINTMENT OF TEMPORARY MEDICAL OFFICER.**

Applications are invited from medical practitioners with special experience of mental deficiency in children.

The salary will be at the rate of £600 per annum, with travelling expenses in accordance with the Council's scale, and the appointment is expected to last for about twelve months.

The Officer will be required to act under the County Medical Officer. The duties will be the examination of all dull and backward children in the county, and the completion of the Board of Education Report Form for those who are mentally defective.

The appointment will be subject to one month's notice by either side.

Applications must be made on the prescribed form which can be obtained from the County Medical Officer, Public Health Department, 29, Thorpe Road, Norwich, to whom they must be returned, accompanied by copies of not more than three recent testimonials, not later than March 19th, 1938.

H. C. DAVIES,
County Offices, Clerk of the County Council.
Thorpe Road, Norwich.

CITY OF BRADFORD.**SANATORIUM—GRASSINGTON.****ASSISTANT MEDICAL OFFICER required.**

Appointment tenable for one year at a salary of £175 per annum, plus board and lodgings.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to the undersigned not later than March 23rd, 1938.

Town Hall, Bradford. N. L. FLEMING.
February 26th, 1938.

COUNTY BOROUGH OF WALSALL.**MANOR HOSPITAL.****ASSISTANT MEDICAL OFFICER.**

Applications are invited from duly qualified persons for the appointment of Assistant Medical Officer (resident) at a commencing salary of £340 per annum, rising by £25 per annum to £425 per annum together with emoluments valued at £125 per annum.

The person appointed should have had special experience in obstetrics and will be responsible, under the direction of the Medical Superintendent, for the Obstetric and Children's Wards and Antenatal Sessions. The Department is supported by a Consultant.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, stating age, professional qualifications and experience, accompanied by not more than three copies of testimonials, should be sent to the Medical Officer of Health, Health Department, Council House, Walsall, not later than March 26th, 1938.

March 3rd, 1938.

COUNTY BOROUGH OF WALSALL.**MANOR HOSPITAL.****JUNIOR ASSISTANT MEDICAL OFFICER.**

Applications are invited from duly qualified persons for the appointment of Junior Assistant Medical Officer (resident). The appointment will be for a period of 12 months and the salary is at the rate of £150 per annum, together with the usual emoluments.

The person appointed will be required to act under the general direction of the Medical Superintendent, and carry out the duties of Casualty Officer and Resident Anaesthetist.

Applications, stating age, professional qualifications and experience, accompanied by not more than three copies of recent testimonials, should be sent to the Medical Officer of Health, Health Department, Council House, Walsall, not later than March 26th, 1938.

March 3rd, 1938.

COUNTY BOROUGH OF WALSALL.**MANOR HOSPITAL.****CONSULTING OBSTETRICIAN AND GYNAECOLOGIST.**

Applications are invited for the above appointment from gentlemen of recognized Consultant rank. The gentleman appointed will be required to conduct a consultative antenatal and gynaecological clinic once monthly at the Manor Hospital, for which a fee of £3 3s. per session will be paid.

The gentleman appointed will also be required to act as Consultant Obstetrician at the Hospital, a fee of £5 5s. being paid for each emergency visit.

Applications to be sent to the Medical Officer of Health, Council House, Walsall, not later than March 26th, 1938.

COUNTY OF KENT.**VENEREAL DISEASES CLINIC, CANTERBURY.**

Applications are invited from registered medical practitioners (male), who are duly qualified in accordance with the regulations of the Ministry of Health, for the **PART-TIME** appointment of **MEDICAL OFFICER** of the above mentioned clinic, which is at the Kent and Canterbury Hospital.

One half-day session will be held each week, and the remuneration will be at the rate of three guineas a session, with an allowance for travelling.

The appointment will be terminable at any time by one month's written notice on either side.

Applications, stating age, qualifications and experience, and accompanied by copies of not more than three recent testimonials, should reach the County Medical Officer of Health, Sessions House, Maidstone, not later than March 17th, 1938.

W. L. PLATTIS,
Sessions House, Clerk of the County Council.
Maidstone.
February 26th, 1938.

CITY OF NORWICH**ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.**

Applications are invited for the post of Assistant Medical Officer of Health and Assistant School Medical Officer, to include the duties of Medical Officer with residence at the Isolation Hospital. Salary £160 per annum (including emoluments) valued at £150 per annum, rising by annual increments of £25 to £170 per annum. Board and lodging at the rate of £20 per annum granted when absent from hospital on leave. The post is designated under the Local Government and Other Officers' Superannuation Act, 1922. For particulars apply to the Medical Officer of Health, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39, 41, 43, 45, 47, 49, 51, 53, 55, 57, 59, 61, 63, 65, 67, 69, 71, 73, 75, 77, 79, 81, 83, ADMINISTRATIVE COUNTY OF LEXX APPOINTMENT OF ASSISTANT SPECIALIST OPHTHALMIC SURGEON.

The County Council of the Administrative County of Lexx invite applications for the above appointment from registered Medical Practitioners, not over 45 years of age, with special experience in all branches of ophthalmology and preferably holding the Diploma in Ophthalmic Medicine, to act under the County Medical Officer of Health.

The salary will be at the rate of £1,700 per annum, and will rise, subject to satisfactory service, by annual increments of £150, to £2,200 per annum.

The person appointed will, at the discretion of the Council, either be provided with a car or will be paid a travelling allowance in accordance with the County Scale for the time being in force.

The person appointed will be required to devote his whole time to the service of the Council, and to perform such duties and to furnish such advice and assistance as may be required, and to reside in such district of the County as the Council may decide. The appointment will be held by the successful candidate during the pleasure of the Council, and will be determinable by the Officer by three months' notice in writing.

The person appointed will be required to pass a medical examination and to contribute 5 per cent. of his salary to the fund established by the County Council under the Local Government and Other Officers' Superannuation Act, 1922.

The appointment will be subject to the Council's Sick Pay Rules and Regulations, a copy of which will be forwarded to the successful candidate.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the County Hall, Chelmsford, not later than 10 a.m. on Friday, March 25th, 1938.

E. S. HOLCROFT,
Clerk of the County Council.
County Hall, Chelmsford.
March 7th, 1938.

BOROUGH OF GRAVELAND, KENT. ASSISTANT MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications for this appointment are invited from registered medical practitioners of not more than 40 years of age; commencing salary £150 per annum, rising by two annual increments of £50, to a maximum salary of £350 per annum.

Candidates must have had at least three years' professional experience and special experience in Ante-Natal and Maternity and Child Welfare work, and the work of the School Medical Service including Refractions. The possession of a Diploma in Public Health is necessary.

The person appointed will be required to devote full time to the duties, and not to engage in private practice. Duties to be performed under the direction of the Medical Officer of Health, and to include work in connection with Air Raid Precautions.

The post will be designated as established for the purposes of the Local Government and Other Officers' Superannuation Act, 1922, and the usual deduction of 5 per cent. will be made from salary. The successful candidate will be required to pass a medical examination by the Medical Officer of Health or an Independent Medical Referee appointed by the Council.

Applications must be made on forms obtainable from the undersigned to whom three recent testimonials (not later than the first post on Wednesday, March 30th, 1938, in envelope endorsed "Assistant Medical Officer.")

Canvassing, directly or indirectly, will disqualify.
H. H. BROWN,
Town Clerk.
4, Woodville Terrace, Gravesend, Kent.
March 7th, 1938.

COUNTY COUNCIL OF THE WEST RIDING OF YORKSHIRE. APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER.

The County Council of the West Riding of Yorkshire invite applications from registered medical practitioners for the appointment of Assistant County Medical Officer, the duties of which will be to act as Venereal Diseases Officer and to assist the Medical Officer in General Public Health Administration.

The salary is £960 per annum. Candidates must be duly registered in Medicine and Surgery, and possess the Diploma in Public Health. The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Form of application and further particulars may be obtained from the undersigned, to whom all applications, together with copies of not more than three recent testimonials, should be addressed so as to be received not later than March 21st, 1938.

County Hall, J. C. RILEY-MCGRATH,
Wakefield. Clerk of the County Council.
March, 1938.

COUNTY BOROUGH OF BLACKBURN. LADY ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly registered women practitioners for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer to act under the direction and supervision of the Medical Officer of Health, who is also School Medical Officer.

The maximum salary will be £700 per annum. The commencing salary will not be less than £400 per annum, and will be fixed according to the qualifications and experience of the successful applicant, and will rise by annual increments of £25 to the maximum of £700.

The person appointed must have had at least three years' postgraduate experience in the practice of her profession and special experience of midwifery and ante-natal work. Special postgraduate experience in the treatment of venereal diseases and of diseases of children, and the possession of a reasonable degree of diploma in Public Health will be deemed additional qualifications.

Applications to be made on forms to be obtained from the Medical Officer of Health, Victoria Street, Blackburn, and returned to him not later than Wednesday, March 23rd, 1938, endorsed "Assistant Medical Officer of Health."

Canvassing, directly or indirectly, will be a disqualification.
T. H. HALL,
Blackburn.
March 7th, 1938.

COUNTY BOROUGH OF SMETHWICK. St. Chad's Hospital, Birmingham. HOUSE SURGEON

Applications are invited from registered Medical Practitioners for the appointment of House Surgeon at the Council's Municipal Hospital. The appointment will be for a period of six months from April 6th, 1938, with salary at the rate of £150 per annum with the usual emoluments. If the successful candidate be reappointed for a further period of six months, the salary will be at the rate of £210 per annum. St. Chad's Hospital contains 145 beds, and the cases treated include general medical, acute surgical and maternity patients. It is staffed by the Honorary Consultants of the Birmingham teaching hospitals.

Form of application may be obtained from the Medical Superintendent, St. Chad's Hospital, Hagley Road, Birmingham, 16, to whom application, endorsed "House Surgeon" and accompanied by copies of three recent testimonials, must be delivered not later than March 17th, 1938.

Canvassing, directly or indirectly, will disqualify.
Council House, FRANK CHAPMAN,
Birmingham. Town Clerk.
February 26th, 1938.

CITY OF STOKE-ON-TRENT. STANFORD SANATORIUM. RESIDENT MEDICAL OFFICER.

Applications are invited for the post of Resident Medical Officer (Male) at Stanford Sanatorium. Candidates must be single. Previous institutional experience in Tuberculosis will be an advantage.

Salary at the rate of £350 per annum, rising by annual increments of £25 to £450 per annum, together with board and lodgings. The selected candidate will act under the immediate direction of the Tuberculosis Officer.

Applications, endorsed "Resident Medical Officer," together with copies of three recent testimonials, to be sent to the undersigned not later than Monday, March 21st, 1938.

Town Hall, E. B. SHARPLEY,
Stoke-on-Trent. Town Clerk.
March 4th, 1938.

THE QUEEN'S UNIVERSITY OF BELFAST.

Applications are invited for the post of TUTOR in OBSTETRICS in the UNIVERSITY. The person appointed will also hold the post of Senior Resident Medical Officer in the Royal Maternity Hospital. Candidates must be graduates of at least two years' standing, and have held previous resident appointments in a teaching hospital. Preference will be given to candidates holding or wishing to obtain higher degrees in Surgery, Obstetrics and Gynaecology, and must be members of a recognized Medical Defence Union.

The appointment in the first instance is for one year, but the Tutor may be reappointed for a further term. Salary £300 per annum. Special facilities are offered to a holder who desires to qualify himself for M.C.D.G. The successful candidate will be expected to take up office on April 1st, 1938.

Further particulars may be obtained from the undersigned to whom applications should be sent on or before Monday, March 21st, 1938.

Queen's University, THE SECRETARY,
Belfast.

MONTGOMERY COUNTY COUNCIL. COUNTY MEDICAL OFFICER AND SCHOOL MEDICAL OFFICER.

Applications are invited from qualified medical men for the above appointment. Candidates must possess a Diploma of Public Health.

The duties will include all statutory duties as County Medical Officer and School Medical Officer, all work required by the Mental Deficiency Committee, the inspection of Midwives and the supervision of the work of the County Dentist and County Health Visitor, control of, and attendance at, Maternity and Child Welfare Centres, refraction work, and prescribing of glasses, with general supervision and control of the various Clinics for School Children and General Supervision of the Medical work under the Public Assistance Committee.

Salary £240 per annum rising, by annual increments of £25 per annum, to £310 per annum, together with travelling allowances on the County Scale.

The appointment will be subject to the approval of the Government Departments concerned and terminable by three months' notice on either side.

The person appointed will be required to devote his whole time to the services of the Council and will not be allowed to engage in private practice, and must reside within easy reach of the Public Health Office at Stratford-on-Avon.

A knowledge of Welsh is desirable. Applications, stating age, qualifications, training and experience of candidates, together with three recent testimonials, must reach the undersigned not later than April 1th, 1938.

Canvassing in any form, oral or written, direct or indirect, will be considered a disqualification.
GEORGE R. D. HARRISON,
Clerk of the County Council.
County Office, Weobool.
March 7th, 1938.

ESSEX COUNTY COUNCIL. APPOINTMENT OF PART-TIME OPHTHALMIC SURGEON

The County Council of the Administrative County of Essex invite applications for the above appointment from registered medical practitioners not over 45 years of age, with special experience in ophthalmology, to act under the County Medical Officer of Health.

Preference will be given to candidates holding an Ophthalmic Hospital appointment and the possession of the Diploma in Ophthalmic Medicine will be considered an additional qualification.

The salary will be at the rate of £200 per annum for the service of a week, together with a travelling allowance in accordance with the County Scale for the time being in force.

The appointment will be held by the successful candidate during the pleasure of the Council, and will be determinable by the Officer by three months' notice in writing.

Applications on the prescribed form, obtainable from the undersigned, accompanied by copies of not more than three testimonials (which will not be returned) should be addressed to me and delivered at the County Hall, Chelmsford, not later than Monday, March 21st, 1938.

County Hall, CHOLCROFT,
Chelmsford. Clerk of the County Council.
March 1st, 1938.

BATH CITY COUNCIL. ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Assistant Medical Officer (Male) at the Bath Sanatorium. Candidates must be single, and should hold the Diploma in Public Health. The officer will be required to work under the direction and supervision of the Medical Officer of Health and to devote whole-time service to the Council.

Salary £600, rising, subject to approval of service, by annual increments of £50 to £700. The post is designated one for superannuation purposes, and the candidate's age must not exceed 45 years.

Application forms and full particulars of the appointment may be obtained from the undersigned, and the form must be received by him not later than March 21st, 1938.

Guildhall, Bath, J. BASIL OGDEN,
March 3rd, 1938. Town Clerk.

CITY OF LINCOLN. RESIDENT MEDICAL OFFICER.

Applications are invited for the appointment of Resident Medical Officer (Male), to be based at the City Hospital and Sanatorium, for a period of 12 months, from registered medical practitioners.

Salary £350 per annum, with board, lodging and laundry. Applications must be made on the prescribed forms not later than March 21st, 1938.

Forms of application and further particulars of the appointment may be obtained from the undersigned.

City Health Department, M. L. BERRY,
Baumgartner Place, Medical Officer of Health,
Lincoln.

EGYPTIAN GOVERNMENT. EGYPTIAN UNIVERSITY. FACULTY OF MEDICINE.

Applications are invited for the post of **PROFESSOR OF DENTAL SURGERY and PATHOLOGY and SUPERINTENDENT of STUDIES in the DENTAL SCHOOL of the EGYPTIAN UNIVERSITY, CAIRO.**

Applicants must possess an English Dental qualification, and have had experience in teaching and administration in a Dental School. Preference will be given to applicants with double qualifications.

The appointment will be on contract for five years, not renewable.

The net salary offered is LE1,200 (approximately £ sterling 1,230) a year, subject to a deduction of Government Stamp Duty, which amounts at present to £ sterling 37. If an official of the Egyptian Government is appointed to the post he will not receive the advertised salary unless it is sanctioned by the Financial Authorities.

A transfer allowance equal to one month's salary will be paid to the successful candidate for travelling expenses at the beginning and again at the end of the contract.

Private practice will not be allowed.

Applications, with details of qualifications, experience and testimonials, should be sent to H.E. the Dean of the Faculty of Medicine, Cairo, so as to be received not later than April 30th, 1938.

COUNTY BOROUGH OF WEST HAM. PUBLIC HEALTH DEPARTMENT.

Applications are invited by the Public Assistance Committee for the post of **ASSISTANT RESIDENT MEDICAL OFFICER (male)**, at Forest Gate Hospital, Forest Lane, E.7, at a salary of £350 per annum, rising by annual increments of £25 per annum to a maximum of £450 per annum, with apartments, rations and laundry, valued for superannuation purposes at £150 per annum, subject to the Council's Regulations as to sick pay, holidays, etc. The salary is inclusive, and any fees received must be paid to the Council.

Candidates must be qualified registered medical practitioners, preference being given to candidates who have had, in addition to a general hospital appointment, an appointment in a hospital with charge of maternity beds.

The number of beds at the hospital is approximately 750, and comprises chronic sick, epileptics and mental defectives, with two maternity blocks.

The successful candidate may be required to serve in any of the Council's other institutions.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, or the Poor Law Officers' Superannuation Act, 1896.

Forms upon which application must be made can be obtained from the Medical Officer of Health, Public Health Department, 88, Romford Road, Stratford, E.15, on the receipt of a stamped addressed foolscap envelope, and should be returned to the undersigned not later than April 2nd, 1938.

Canvassing members of the Council, either directly or indirectly, is prohibited, and will disqualify.

CHARLES E. CRANFIELD,
Public Assistance Officer, Town Clerk.
Union Road, Leytonstone, E.11.
March 4th, 1938.

COUNTY COUNCIL OF SUTHERLAND. PARISHES OF KILDONAN AND LOTH

Applications are invited from registered Medical Practitioners for the appointment of **LOCAL MEDICAL OFFICER of the Parishes of Kildonan and Loth, in the County of Sutherland.**

Salary from the County Council in respect of services, income from other sources, Highlands and Islands Medical Service Fund, and the panel practice approximately £533 per annum, with house and private practice in addition.

Applications, with statement of qualifications and experience, accompanied by twenty-two copies of three recent testimonials and of the application, to be lodged with the undersigned on or before March 31st, 1938.

County Clerk's Office, **ARCHD. ARGO,**
Golspie, County Clerk.
March 5th, 1938.

COUNTY BOROUGH OF PRESTON. Sharoe Green Hospital. (250 Beds.)

JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER (FEMALE).

Applications are invited from fully qualified and registered Practitioners for the above appointment. Salary at the rate of £100 per annum, with full board and residence. The appointment will be for a period of six months and can be renewed for a period not exceeding six months.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should reach the Medical Superintendent not later than first post on March 26th, 1938.

COUNTY COUNCIL OF DURHAM. ASSISTANT WELFARE MEDICAL OFFICER.

The County Health Committee invite applications for an Assistant Welfare Medical Officer (woman) at a commencing salary of £500 per annum, rising by annual increments of £25 to £700 per annum. Travelling allowance will be paid by the County Council in accordance with a scale to be approved from time to time.

The appointment will be held subject to three calendar months' notice on either side, and to the following conditions:

(1) The Officer appointed must be a registered medical practitioner between the ages of 25 and 55 years, must devote the whole of her time to the duties of the office, and must not engage in private practice.

(2) She should either have had a previous appointment as Medical Officer of an ante-natal clinic, with the approval of the Minister of Health, or have had at least three years' experience in the practice of her profession and special experience of practical midwifery and ante-natal work. The holding of a diploma in Public Health will be deemed an additional qualification for the post.

(3) She will be subject to the directions of the County Medical Officer of Health.

(4) She will be required to reside in Durham City, or such other place as required by the Council.

(5) She must be prepared, if called upon, to act as locum tenens to other members of the medical staff of the County Medical Officer of Health.

(6) The appointment will terminate on marriage.

(7) The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, endorsed "Assistant Welfare Medical Officer," with copies of not more than three recent testimonials, must be addressed to the County Medical Officer of Health, Shire Hall, Durham, and must be received by him not later than Monday, March 28th, 1938.

Shire Hall, Durham, **J. K. HOPE,**
March 5th, 1938. Clerk of the County Council.

COUNTY COUNCIL OF DURHAM. APPOINTMENT OF TEMPORARY ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the post of Temporary Assistant Medical Officer of Health (male), at a commencing salary of £600 per annum. The appointment is subject to one month's notice on either side, and will terminate at the end of two years. Travelling and subsistence allowances will be paid in accordance with the Council's scale.

Applicants must be registered medical practitioners under the age of 55 years, and should if possible possess a qualification in Public Health and have held a post in an Infectious Diseases Hospital. Experience in the examination and certification of mentally defective children and adults will be an additional recommendation.

The officer appointed will be required to devote the whole of his time to the duties of the office, and will not be allowed to engage in private practice. He will also be required to undertake such other Public Health duties as may be allotted to him by the County Medical Officer of Health, under whose direction he will work.

Applications, stating age, qualifications and experience, and accompanied by copies of not more than three recent testimonials, should be forwarded to the County Medical Officer of Health, Shire Hall, Durham, not later than first post on Monday, March 28th, 1938.

Shire Hall, Durham, **J. K. HOPE,**
March 5th, 1938. Clerk of the County Council.

BOROUGH OF ACCRINGTON. DEPUTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications for the above post are invited from registered medical practitioners of either sex. Candidates should have had sound post-graduate experience in general clinical work, including the diseases of children, and preference will be given to a person possessing a Diploma in Public Health or an equivalent registrable qualification.

The officer appointed will be required to carry out duties in all branches of the Public Health and School Medical Services, including both clinical and administrative work. He, or she, will work under the direction of the Medical Officer of Health and will act as that officer's Deputy.

The salary will be at the rate of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum. The post will be designated for superannuation purposes.

Forms of application and particulars of the appointment and its terms and conditions may be obtained from the undersigned, to whom the completed form must be returned not later than Monday, March 28th, 1938.

Town Hall, Accrington, **W. H. WARHURST,**
March 9th, 1938. Town Clerk.

SURREY COUNTY COUNCIL. BOTLEYS PARK COLONY (CERTIFIED INSTITUTION FOR MENTAL DEFECTIVES). Near Chertsey, Surrey.

APPOINTMENT OF DEPUTY MEDICAL SUPERINTENDENT.

Applications are invited from registered medical practitioners (male) for the whole-time appointment of Resident Deputy Medical Superintendent at the above-mentioned Certified Institution. The first section of the Colony, which is now in course of erection, will provide accommodation for 1,200 patients and the necessary resident staff, and will eventually provide 1,500 patient beds. In addition, there is accommodation for another 300 patients in an immediately adjacent institution, which is under the same administration as the main colony.

Commencing salary £720, rising by annual increments of £25 to a maximum of £820 per annum, with emoluments valued for superannuation purposes at £30 per annum.

Applicants, who must be in possession of the Diploma of Psychological Medicine, should have had practical experience in a large Mental Institution, preferably for Mental Defectives. Age not to exceed 40 years.

The appointment will be subject to the provision of the Asylums and Certified Institutions (Officers' Pensions) Act, 1915, and to the Council's Staffing Regulations. The person appointed will be required to undergo a medical examination, and to commence his duties on June 1st, 1938.

Applications, stating age and whether married or single, accompanied by copies of three recent testimonials, must reach the undersigned not later than Monday, April 4th, 1938. The envelope should be marked "Botleys Park Deputy Medical Superintendent."

DUDLEY AUKLAND,
Clerk of the Council
Mental Hospitals Department,
County Hall, Kingston-upon-Thames.
March 8th, 1938.

SURREY COUNTY COUNCIL. ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of an Assistant Medical Officer (male). Applicants must possess a qualification in Public Health, and should have had experience in the Medical Inspection of School Children and in Maternity and Child Welfare work.

The officer appointed will be required to undertake such other Public Health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County of Surrey, and devote his whole time to the work.

Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health and of the Board of Education, to the successful candidate passing a medical examination, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Staffing Regulations of the Council, which provide, *inter alia*, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Wednesday, March 16th, 1938.

Canvassing, directly or indirectly, will disqualify.

DUDLEY AUKLAND,
Clerk of the County Council
County Hall, Kingston-upon-Thames.
March 9th, 1938.

COUNTY BOROUGH OF GRIMSBY. Corporation Hospital and Sanatorium. RESIDENT MEDICAL OFFICER.

Applications are invited for the post of **RESIDENT MEDICAL OFFICER (male)** at the above Hospital, which has 93 beds for pulmonary and surgical tuberculosis and 72 for infectious diseases.

Candidates must be unmarried and have previous resident hospital experience. Salary £700 per annum, rising by annual increments of £25 to £750 per annum, plus board, residence and laundry. The appointment is to be for one year in the first instance. The post is a designated one under the Local Government and Other Officers' Superannuation Act, 1922.

Forms of application may be obtained from the Medical Officer of Health, 104, Victoria Street, Grimsby, and should be returned to the undersigned "Resident Medical Officer," not later than Thursday, March 31st, 1938.

CHARLES H. BESSELL,

February 21st, 1938. Secretary

THE HOSPITAL FOR SICK CHILDREN, GT. ORMOND ST., LONDON, W.C.1

APPOINTMENTS

TO BE MADE PREPARATORY TO THE OCCUPATION OF THE

NEW HOSPITAL

A RESIDENT MEDICAL SUPERINTENDENT

who is to be the Senior Resident Officer, is required on the 1st May, 1938. Salary £200 per annum.

This appointment is tenable in the first instance for one year, but may be held for a period of two years, subject to re-election.

The duties will include the medical administration of the Hospital and medical supervision of the Nursing and Domestic Staffs.

Candidates must be unmarried, possess a legal qualification to practice and have held a responsible resident appointment at a General Hospital. Special experience in infectious diseases is desirable.

Candidates for the above appointments must attend at the Hospital to appear before the Joint Committee at 4.45 p.m. on Wednesday, 6th April, 1938.

Further particulars and forms of application, which must be completed and returned by noon on Monday, 4th April, 1938, are obtainable from the undersigned.

March, 1938.

Two HOUSE PHYSICIANS and

Two HOUSE SURGEONS

are required on the 15th April, 1938.

These appointments are tenable for six months. Salaries at the rate of £50 per annum.

Candidates must be unmarried, possess a legal qualification to practice and have held a responsible resident appointment at a General Hospital.

AN OUT-PATIENT AURAL REGISTRAR

(part-time)

is required on the 1st May, 1938. Salary £175 per annum.

This appointment is tenable in the first instance for one year, but may be held for a period of two years, subject to re-election.

Candidates must possess a legal qualification to practice and have held a responsible resident appointment at a General Hospital.

Candidates for the above appointments must attend at the Hospital to appear before the Joint Committee at 4.45 p.m. on Wednesday, 6th April, 1938.

HERBERT F. RUTHERFORD, Secretary.

CITY OF LIVERPOOL.

RESIDENT ASSISTANT MEDICAL OFFICER (MALE) FOR ORTHOPAEDIC WARDS, ALDER HEY CHILDREN'S HOSPITAL.

Applications are invited for the above appointment at the Alder Hey Children's Hospital (956 beds), Liverpool, to take up duty immediately, for six months, with the option of renewal after this period, at a salary of £200 per annum, together with the usual residential allowances.

180 beds are set aside for Orthopaedic Diseases of Children, and these include open-air wards for surgical tuberculosis. Also there is a large amount of fracture and other orthopaedic work of an acute nature. There are three Visiting Orthopaedic Surgeons, the senior being Mr. T. P. McMurray, M.Ch., F.R.C.S. In addition to the Orthopaedic work, routine duties in the Hospital will have to be carried out under the direction of the Medical Superintendent. Previous experience in Orthopaedic work is desirable, and the Hospital affords ample opportunity for gaining special experience in this work. Canvassing will be deemed a disqualification.

Applications to be made upon forms obtainable from the Medical Officer of Health, Municipal Annex, to be endorsed "Resident Assistant Medical Officer (Orthopaedic)," and returned to the undersigned so as to be received not later than Wednesday, March 23rd, 1938.

Municipal Buildings, W. H. BAINES,
Liverpool, 2. Town Clerk.
March, 1938.

COUNTY OF DORSET.

APPOINTMENT OF COUNTY PATHOLOGIST.

The Dorset County Council invite applications from registered medical practitioners for the appointment of a County Pathologist, at a commencing salary of £750 per annum, rising to £950 by biennial increments of £50.

Applicants must have specialized in Pathology and Biochemistry, and have had considerable experience in a Pathological Department.

The Officer appointed will be required to devote his whole time to the duties of his office, and will be in charge of the work of the County Laboratory, Dorchester, acting under the administrative control of the County Medical Officer.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass the necessary medical examination.

Applications, on a prescribed form, which may be obtained from me on receipt of a stamped addressed foolscap envelope, must be forwarded so as to be received not later than Monday, April 4th, 1938.

Canvassing, either directly or indirectly, will be a disqualification.

County Offices, C. P. BRUTTON,
Dorchester. Clerk of the County Council.
March 4th, 1938.

CITY MENTAL HOSPITAL,

Humberstone, Leicester.

ASSISTANT MEDICAL OFFICER (Male).

WOOLWICH AND DISTRICT WAR MEMORIAL HOSPITAL.
Sectory H.I.I. London, S.E.15

General Hospital—112 Beds.

**(a) RESIDENT MEDICAL OFFICER.
(b) HOUSE SURGEON.**

The Board of Management invites applications from suitably qualified male candidates for the following posts—

(a) Resident Medical Officer. This appointment, which will be the second senior of five residents, will be for one year with effect from April 1st, 1938, and renewable for a further twelve months, if approved by the Board of Management. The salary will be £150 per annum, plus board, residence and laundry, and the duties will include (i) Medical Registrar and (ii) Resident Pathologist.

(b) House Surgeon for six months from May 1st, 1938. Remuneration at the rate of £100 per annum, plus board, residence and laundry. In addition to his surgical duties the House Surgeon will have the care of a Maternity Unit of 3 beds.

Short-listed candidates selected for interview will be required to meet the Appointments Committee (at the Hospital) on Thursday, March 14th, 1938, at 4.45 p.m. The closing date for receipt of applications (to be submitted on the prescribed form obtainable from the Secretary) is Monday, March 21st, 1938.

R. S. G. HUTCHINGS,
Secretary.

WORCESTER COUNTY AND CITY MENTAL HOSPITAL.
Fosse, Near Worcester.

Applications are invited for the post of ASSISTANT MEDICAL OFFICER. Applicants must be male, single, under 35 years of age and fully qualified in medicine and surgery. Commencing salary £350, rising by annual increments of £25 to a maximum salary of £450 per annum, together with furnished apartment, board, laundry, and attendance. A full certificate of the Board of the Hospital is required.

If the selected candidate holds or obtains a Diploma in Psychological Medicine, Experience in Anaesthetics will be a recommendation. The appointment is subject to the provisions of the Asylum Officers' Superannuation Act, 1920. Applications, stating age and full particulars of qualifications and experience, accompanied by copies of three recent testimonials, to be forwarded to the Medical Superintendent not later than Saturday, March 26th, 1938.

WESTMINSTER HOSPITAL, S.W.1

A vacancy has been declared the day in the office of ASSISTANT PHYSICIAN to this Hospital. Gentlemen desirous of becoming candidates must be Fellows or Members of the Royal College of Physicians of London. Each candidate will be required to transmit a certificate of his age, and to submit three copies of his application, with testimonials, to the undersigned not later than Friday, April 1st, 1938, and to attend the meeting of the House Committee at 4.15 p.m. on Tuesday, April 5th, 1938. The appointment is an open one.

By Order of the House Committee.
CHARLES M. POWER,
Secretary.

March 8th, 1938.

ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE.

Swanley, Kent.
(100 Beds for Children with Bone and Joint Tuberculosis and other Orthopaedic Conditions.)

Applications are invited for the post of **SECOND RESIDENT MEDICAL OFFICER**. Candidates must be unmarried and fully qualified, and should preferably hold the Diploma of F.R.C.S.(Eng.). The successful candidate will be required to take up duty on May 1st. The appointment is for six months, with eligibility for re-election. Commencing salary £250 to £300 yearly, according to qualifications and experience. Board and lodging will be provided.

Applications, stating age and giving full particulars of qualifications and previous surgical experience, with copies of two testimonials, should be sent not later than March 21st to the undersigned at the London Offices, 107, Southampton Row, London, W.C.1, from whom further particulars of the duties and conditions of the appointment can be obtained.

STANLEY SMITH,
Secretary.

March 11th, 1938.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

Applications are invited for the following posts:
(a) **HOUSE PHYSICIAN**, vacant on May 1st.
(b) **HOUSE SURGEON** to the Special Departments, with care of beds for ear, nose and throat, eye, gynaecological and maternity cases, vacant on May 1st.

Each appointment is tenable for a period of six months, but is terminable at an earlier date by one month's written notice on either side. The salary of each officer will be at the rate of £130 per annum, with board, residence and laundry.

Candidates (male), who must be unmarried and duly registered, are requested to forward their applications, stating age, qualifications, etc., together with copies of not more than four testimonials, to the undersigned, on or before Wednesday, March 23rd, 1938.

J. A. BEARDSALL,
Secretary-Superintendent.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

Applications are invited for the post of **RESIDENT ANAESTHETIST AND EMERGENCY OFFICER** (male). The appointment will be for three months from April 1st, 1938. Salary at the rate of £130 per annum, with board, residence and laundry. Candidates, who must be unmarried and duly registered, are requested to forward their applications, stating age, qualifications, etc., together with copies of not more than four recent testimonials, to the undersigned on or before Wednesday, March 23rd, 1938.

J. A. BEARDSALL,
Secretary-Superintendent.

BRISTOL HOMOEOPATHIC HOSPITAL
(Bruce Melville Wills Memorial),
Bristol, 6.

The Board of Management invite applications for the appointment of **RESIDENT MEDICAL OFFICER** to commence duty on April 1st next, at a salary of £120 to £150 per annum, according to experience, with board, laundry and accommodation.

The Hospital is a modern one with the latest equipment, and a most comfortable suite of rooms is provided in the institution.

Opportunity for good Surgical and General experience.

Applications should be forwarded with copies of three recent testimonials, not later than March 26th, addressed to the undersigned.

H. HUNTER, Lt.-Colonel,
Secretary.

BIRMINGHAM & MIDLAND EYE HOSPITAL.
(114 Beds.)

Applications are invited from duly qualified medical practitioners for the post of **HOUSE SURGEON** at the above Hospital.

Salary £130 per annum (rising to £150 at the end of six months' satisfactory service), and £10 laundry allowance.

The Resident Staff consists of a Resident Surgical Officer and three House Surgeons.

Applications, with testimonials and evidence of registration, must be received not later than Thursday, March 24th, 1938.

Church Street, J. W. PEARCE,
Birmingham, 3. General Superintendent.

BIRKENHEAD GENERAL HOSPITAL.
(156 Beds.)

Applications are invited for the following Resident (male) posts, for the six months commencing April 1st, 1938.

HOUSE PHYSICIAN. Salary £100 per annum.
CASUALTY OFFICER. Salary £100 per annum.

Both with board, residence and laundry.
Applications, stating age, nationality and qualifications, together with three recent testimonials, to reach the undersigned as soon as possible.

W. H. DANIELS, F.C.I.S.,
Secretary-Superintendent.

DEVONSHIRE ROYAL HOSPITAL,
Buxton, Derbyshire, (300 Beds.)
(A National Hospital for Rheumatism and Allied Diseases.)

RESIDENT MEDICAL OFFICER (male), salary £200 per annum, or **HOUSE PHYSICIAN** (male), salary £150, rising to £175 after three months' service (and prospects of promotion to Resident Medical Officer), with board-residence and laundry. Candidates must be fully qualified and registered. The appointments are for a minimum period of six months, and may be extended for a further period of six months.

Applications, endorsed "Medical Appointments," stating age, experience and qualifications, and whether application is made for one or either post, together with copies of three recent testimonials, must be forwarded without delay to the undersigned, from whom any further particulars may be obtained.

Considerable orthopaedic experience is available, and the appointments offer special facilities for gentlemen preparing a thesis or wishing to undertake special work, as the Hospital contains all the necessary laboratory and other facilities for research. Canvassing will disqualify.

By Order of the Committee of Management,
A. PRESTON TURNER,
General Superintendent and Secretary.

BRIGHTON COUNTY BOROUGH MENTAL HOSPITAL,
Haywards Heath, Sussex.**APPOINTMENT OF THIRD ASSISTANT MEDICAL OFFICER.**

The Visiting Committee are prepared to receive applications from medical men for the above post. No married quarters are provided. LONDON

BRITISH MEDICAL ASSOCIATION

TAVISTOCK SQUARE

A FEW SPECIALITIES OF **F. DAVIDSON & CO.**
THE PIONEERS OF SELF-ILLUMINATED DIAGNOSTIC INSTRUMENTS
 143-149, GREAT PORTLAND STREET, LONDON, W.1. (Est. 1890.)

"STREAMLINE" CAUTERY HANDLE

Provides a comfortable yet steady grip. Trigger "make and break." Unobstructed view of burner which plugs in either horizontal or vertical position. Free of all connecting screws. Cords plug in at extreme base, free of operator's hand. Ebonite casing. Tungsten contacts.

No. 26P. Handle and Cords.
 Price complete, £1 17 6.

'DAVON' ACCUMULATOR CAUTERY & LIGHT SET

No. 18C. 0 to 4 Volts.
 Actual capacity 20 ampere hours.

This constitutes an achievement in the production of a highly efficient apparatus at a moderate cost.

No. 18C comprises a 4-volt glass accumulator made without plate separators. Concealed rheostats for cautery and light, actuated by rotating knobs on the lid, permit of very easy and gradual adjustment. Separate terminals for cautery and light allow of both being employed at the same time.

In Walnut Box with strap handle.

Price, £4 4 0.

"DAVON" A.C. TRANSFORMERS

EARTH FREE AND WITH OUR ABSOLUTE GUARANTEE BEHIND THEM

Made on the same principle as the heavy and expensive industrial ones.

No. 83. For LIGHT and for CAUTERY

Size 11 x 8½ x 6 in.
 Weight 15½ lbs.
 Price £6 10 0.

Will illuminate Surgical Lamps of from 1 to 12 volts, and up to 2 amperes.

Will give an output for Cautery up to 30 amperes.

A COMPLETE POCKET OUTFIT

for Eye, Ear, Nose and Throat Examination, in handsome leather covered velvet-lined case.

No. 512A. Comprising Lighting Tube, 2 Mirrors, Fitting with 3 Aural and 1 Nasal Specula, Magnifier, the "Davon" combined Electric Ophthalmoscope and Retinoscope, 3-volt Battery in Handle, also switch and cord for use from "Davon" Battery.

Size 7½ x 4½ x 2 in. Price, complete, £9 0 0.

No. 512, without Ophthalmoscope, size 6½ x 4½ x 2 in. Price, £5 5 0.

Other Outfits with "Davon" Battery from £3 12 6.

NOTE.—The "Davon" Dry Battery has a well-earned reputation as the only really dependable one on the market. Many of our clients have used it intermittently for three years and more.

Price, 7s. 6d. post free in U.K.

"DAVON" DIRECT VISION OPHTHALMOSCOPE

Gives a clear, magnified image of the fundus without corneal reflex, in bright light, without dilatation of the pupil and at an approximate distance of 7 in. from the patient. Price complete in leather wallet and spare bulb. £5 0 0.

'DAVON' LARYNGO-PHARYNGOSCOPE

THE INSTRUMENT WITH PERFECT OPTICAL SYSTEM, PERFECTLY FINISHED

"I find your laryngo-pharyngoscope a most useful instrument and have been able to obtain excellent views of the posterior nasopharynx and larynx with it."

M.R.C.S., L.R.C.P.

With Protecting Mask. Handle and Cord. £5 0 0.

THE "DAVON" ALL-METAL STETHOSCOPE

Price complete in Purse Bag. £1 6 0.

"IT IS EASILY THE BEST STETHOSCOPE I HAVE EVER USED."

FULL DETAILS OF THE ABOVE AND OF OTHER "DAVON" SPECIALITIES WOULD GLADLY BE FORWARDED ON REQUEST.

In the treatment of MACROCYTIC ANAEMIAS

This palatable liquid extract of hog's stomach contains Hæmopoietin in stable solution. The stomachs are treated immediately after killing to extract the *Antianæmic Factor* in active condition producing a bland liquid of pleasant flavour, to which the name HOGASTRIN has been given.

A dose of two teaspoonfuls in a little water three times a day for a fortnight, then reduced to one teaspoonful, will invariably give good results in the treatment of all Macrocytic Anæmias.

For inspection sample and literature apply to the manufacturers:

GILES SCHACHT
AND CO.

CLIFTON, BRISTOL, 8

Manufacturing chemists for
over a century.

Packed in 4 oz., 8 oz. and 16 oz. bottles.

HOGASTRIN

Orava Castle . . Czecho-Slovakia

A delightful scene . . . bringing to mind, maybe, many a happy day during a well-earned rest. And talking of travel, may we suggest to practitioners when next this subject looms on the horizon, that whether they are themselves taking a holiday for pleasure, or recommending their patients to take one for health, The World-wide Service of Cook's is at their disposal . . . giving sound advice on all phases of travel . . . handling all those worrying details that can so easily mar the enjoyment of a holiday.

Advice without obligation from any branch of

CINERADIOGRAPHY. RUSSELL J. REYNOLDS.

The object of this text-book is to provide a comprehensive survey of the present position of X-ray diagnosis. Diagnostic radiology is becoming an increasingly complex speciality, and it is difficult for one person to be equally expert in all its branches. The Editors have secured the help of collaborators, both radiological and clinical, who are distinguished in particular branches of the subject. It is hoped it will be of value not only to the post-graduate student of radiology, but also to the clinician.

The illustrations. The greatest possible care has been taken in the preparation of the blocks, the selection of the paper, and also in the printing, the aim being to produce a worthy record of British work in the field of Radiology.

Prospectus of the work, with a Summary of Contents, Specimen Pages and Order Form, post free on application. Orders may be placed through any bookseller.

B.M.J.

This Annual aims at providing year by year in the barest economy of words and with the greatest clarity, the latest methods of diagnosis and treatment. The chapters are authoritative statements of up-to-date teaching, and to the busy practitioner serve as a "refresher" course—a far fuller course, in fact, than any that could be attended in person.

SOME SUBJECTS

PAIN IN THE ILIAC FOSSA

Sir John Frazer, K.C.V.O., M.C., M.D.,
F.R.C.S.Ed., Regius Professor of Clinical
Surgery, University of Edinburgh.

DIARRHOEA

Philip Manson-Bahr, C.M.G., D.S.O., M.D.,
F.R.C.P., Director of Clinical Tropical
Medicine, London School of Hygiene and
Tropical Medicine.

HEADACHE IN INFANCY

W. G. Wyllie, M.D., F.R.C.P., Physician to
Out-patients, Hospital for Sick Children,
Great Ormond Street.

FRACTURES OF THE UPPER END OF THE FEMUR

Ernest W. Hey Groves, M.D., F.R.C.S.,
Emeritus Professor of Surgery, University
of Bristol.

THE DIAGNOSIS OF CONSTIPATION

S. W. Patterson, M.D., D.Sc., F.R.C.P.,
Ruthin Castle, North Wales.

INDICATIONS FOR LIGHT THERAPY IN THE RHEUMATIC DISEASES

Albert Eidinow, M.B., B.S.Lond., Hon. Con-
sulting Physician to the Radium Institute,
London.

INTERNAL DERANGEMENTS OF THE KNEE

Arthur E. Porritt, M.A., M.Ch., F.R.C.S.,
Surgical Unit, St. Mary's Hospital, London.

THE TREATMENT OF HEART BLOCK

C. W. Curtis Bain, M.C., D.M., Physician,
Harrrogate General Hospital.

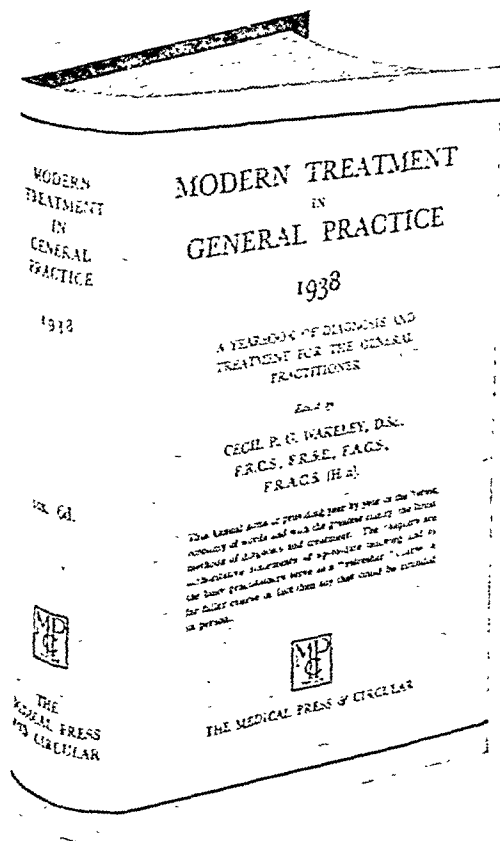

INFLUENZA AND ITS TREATMENT

F. G. Hobson, D.S.O., M.A., D.M.Ox.,
F.R.C.P., Hon. Physician, Radcliffe
Infirmary and County Hospital, Oxford.

OF INTEREST TO EVERY MEDICAL PRACTITIONER

A proper understanding of Physical
Medicine is becoming increasingly
essential in everyday practice.

THE . . .

British Journal of Physical Medicine

is the only British Journal dealing exclu-
sively with Physiotherapy, which
includes Actinotherapy, Electrotherapy,
Radiotherapy, Manipulation, Remedial
Exercises, Massage, Diet, etc.

In view of the rapidly increasing recognition of the importance of Physical Medicine, the Journal has been considerably altered both with regard to its editorial matter, and also in size, format, and typography. The new British Journal of Physical Medicine, while, as in the past, providing its readers with the latest and most authoritative opinions on all matters appertaining to physical medicine, includes shorter, essentially practical articles, and a variety of other information designed to be instructive to the general practitioner.

HAVE YOU EVER DRIVEN A FORD V-8 "30"?

If not, you have still something to learn about twentieth-century motoring!

Performance, refinement of performance, ease of control, wonderful acceleration, remarkable flexibility in heavy traffic, exhilarating speed on the open road, coupled with extreme comfort, luxurious restfulness, and complete controllability, under all conditions—these are some of the outstanding merits of the FORD V-8 "30." No other car in the history of public competition has put up such a sweeping demonstration of performance as did the Ford V-8 in this year's Monte Carlo Rally—5 placings out of the first 7, 19 trophies, including the premier award, the best performance by lady drivers, and the best team-performance.

See the Ford V-8 "30" at the Local Ford Dealer's Depot. Drive it yourself.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S. (Eng.)

"It is almost unnecessary to say anything in recommendation of this well-known work, though it is a pleasure to record once again that it fully maintains the very high standard of its predecessors."

—British Journal of Surgery.

Bristol: JOHN WRIGHT & SONS, LTD.

RECENTLY PUBLISHED. Third Fully Revised Edition. Large 8vo. 352 pages. With 316 Illustrations, of which a large number are in Colour. 50s. net, postage 3d.

EMERGENCY SURGERY

By HAMILTON BAILEY, F.R.C.S. (Eng.)

REVIEWS FROM PREVIOUS EDITIONS.

"Mr. Bailey has achieved a great feat in writing this book, and many generations of medical men will thank him for it. . . . We do not see how this book could be bettered in any way."

—Medical Press and Circular.

"Mr. Hamilton Bailey has just cause to be proud of this volume, which can claim to be equal, and in many ways superior, to any book on the subject published hitherto."

—British Medical Journal.

FOR OVER 130 YEARS

Since 1807, the House of Maw has been serving the Medical Profession faithfully and well. Behind the name Maw is a vast organization which has been built up by supplying goods of reliable quality at reasonable prices and giving efficient service.

Maws are also actual manufacturers; they make Surgical Dressings, Clinical Thermometers, Surgical Appliances, etc., at their Barnet Factories. They carry the dual responsibility of Manufacturers and Wholesalers, and spare no effort to ensure satisfaction to their customers.

Despite its great age the House of Maw keeps abreast of the times and is one of the most up-to-date firms in the trade.

NEXT TIME YOU REQUIRE:—

TEN FOR SIXPENCE—TWENTY FOR ONE SHILLING

**'Gas fires kill
draughts but cure
stuffiness' says**

Mr. THERM (of Harley Street)

If you were to go into a room fitted with a modern gas fire, fill it with smoke, and then light the fire, you would see the smoke being gently but firmly sucked up the flue. In about twenty minutes the room would be clear!

A modern gas fire changes the air in a room three or four times every hour. It does so quietly and unobtrusively, creating no uncomfortable draughts. Stuffiness is equally impossible. That is because the modern gas fire emits an unusually large proportion of the shorter infra-red rays which warm the room (and its occupants) without drying or overheating the air.

GAS for healthy heat

ISSUED BY THE BRITISH COMMERCIAL GAS ASSOCIATION

Why 2 Wavebands?

With "Dorno" Filter
(Wave-band
• 4350-2900 A.U.)

Without Filter
(Wave-band
4350-1850 A.U.)

Because in modern actino-therapy practice it has been established that the majority of cases can be divided in two groups:—

- 1 Cases which respond best to treatment with the wavelengths found in the natural solar spectrum (4350-2920 A.U.).
- 2 In certain skin diseases where the shorter or non-terrestrial wavelengths emitted by the lamp can be beneficially applied.

The "Dorno" Filter, the feature which permits the user to select the wave-band according to the case, is exclusive to the 'BIOSOL'—the U.V. lamp with the international reputation. Users of carbon arc lamps in particular, welcome the 'BIOSOL' as a means of securing all the conveniences of the electronic discharge burner without the disadvantages of the shorter wavelengths. No longer is it necessary to resort to specially cored carbons with a different grade for skin work. With the 'BIOSOL,' where the production of a strong erythema is the first consideration it is only necessary to remove the "Dorno" Filter. The two essential wavebands are there in one lamp! Write today for a copy of Publication No. X. 601 which explains why the 'BIOSOL' has so many points to commend it. Use the coupon below.

The Ideal Spring Tonic

Livogen provides the ideal spring tonic for use in those varying conditions of lowered vitality which are so widespread at the end of the winter and in the early days of spring. These conditions, manifested in asthenia, lassitude, lethargy and debility, are often extremely difficult of exact diagnosis, but physicians everywhere report that the administration of Livogen is followed by a restoration of energy, increased appetite and a general return to normal conditions.

WHOOPING COUGH

Detoxicated Whooping Cough Vaccine (Genatosan) has proved remarkably successful. Reports received from medical practitioners state that it usually reduces the frequency of the paroxysms after the first injection, and subsequent injections almost invariably clear up the condition. Owing to the elimination of the toxic elements of the germ during the process of manufacture, this vaccine may be given to infants and young children, in doses sufficiently large to produce the desired therapeutic effect, with an absence of harmful reaction.

The following is typical of many reports received from physicians:—

"I have been making a somewhat extensive use of your Detoxicated Vaccine for Whooping Cough, and am pleased to say that the results have been almost invariably gratifying. In nearly all my cases the very distressing symptoms have disappeared after the third injection." ————— M.D.

Additional information regarding this Vaccine will gladly be supplied on request.

★ A Physiologic Washing of the Mucous Membrane

★ ARGYROL BRUND SILVER VITELLIN

Rhinologists are agreed that the most satisfactory results in nasal infections follow the use of non-irritating and non-toxic agents—of which Argyrol solution is a singular example.

A noted rhinologist, writing on the subject of acute rhinitis, says that "Argyrol solution, applied on a small cotton pledget, will increase the flow of mucus, thus producing a physiologic washing of the membrane."

This salutary effect is emphasized by Dowling and others as the outstanding characteristic influence of Argyrol in the presence of infection of the nasal airways.

In all mucous membrane affections, whether primary or secondary to some other condition, Argyrol solution stands in a class by itself — *sui generis*, owing to its unique chemical composition which is different from all other silver salts. The prototype mild silver protein, it has never been successfully duplicated. No other silver product contains silver in the same chemical and physical state nor protein of a similar high quality and suitability. Insistence on having the name ARGYROL on all solutions ordered or prescribed, will ensure the clinical results you expect.

Cystopurin

(Registered Trade Mark)

The ideal urinary antiseptic for oral administration!

- | | |
|---|--|
| 1 Produces no gastric irritation or toxic symptoms. | 5 Acts from the renal pelvis downwards. |
| 2 Is readily absorbed from the gut and excreted in the urine. | 6 Is active in either acid or alkaline urine. |
| 3 Causes no renal irritation. | 7 Perfectly safe for use in febrile conditions. |
| 4 Renders the urine bactericidal in low concentrations. | 8 Acts on all causative organisms of urinary infections. |

CYSTITIS

From information received:—

"The patient was myself, aged 66 years. Owing to the cold severe weather I had contracted a semi-acute attack of cystitis with strangury, frequency of micturition, inability to retain urine in bladder, urine full of mucus and alkaline in reaction. I took two tablets of Cystopurin in a tumbler of water three times a day, and in 24 hours the pain and frequency were relieved. In 48 hours the urine was clear and normal in reaction."

"I find that Cystopurin is most effective in cutting short attacks of cystitis and relieving the frequency and pain which accompany micturition. The fact that IT EXERCISES ITS EFFECTS EQUALLY IN ALKALINE OR ACID URINE is a great help."

"I have had excellent results with Cystopurin in a case of cystitis that had proved difficult to cure with other urinary antiseptics. In this case of a woman of 50, the pain and frequency cleared up after three days of Cystopurin, and the urine was rendered sterile—a very gratifying result."

"I used Cystopurin in an obstinate case of cystitis. This improved rapidly, and I consider your preparation more useful for this purpose than other urinary antiseptics I have used."

Supplied in bulk and in tubes of 20 tablets for dispensing purposes.

A STEP FORWARD in infant feeding

Over 300 physicians report
excellent results with remarkable
modifier of cow's milk

KARO, a natural blend of carbohydrates, has been used abroad for many years, with remarkable success, for modifying fresh cow's milk and milk powders for artificially-fed infants.

Recently, a number of physicians were asked to test Karo clinically. The results have been most gratifying. The gist of the letters received from over 300 physicians confirms the opinion of Karo given in a book on infant nutrition by a medical author.

"We have found it (Karo) the most satisfactory form of carbohydrate in the feeding of normal and most sick infants."

The addition of Karo to cow's milk or milk

powder produces results fully equivalent to mother's milk.

A Karo-and-milk mixture has also been found of outstanding value in the case of sickly children—especially those suffering from marasmus, acidosis, cyclical vomiting, diarrhoea, constipation, and all kinds of biliousness, indigestion and nutritional disorders.

Costs about 1½d. a day

Karo is of special benefit to mothers who cannot afford expensive diets for their bottle-fed babies. A 1-lb. tin, costing 1/3, provides a ten days' supply for a three-months-old baby—a cost of 1½d. a day. The price of the 2-lb. tin has recently been reduced to only 2/-.

ANALYSIS OF KARO

RELIEF OF MENOPAUSAL SYMPTOMS

BY MEANS OF

OESTROFORM

Oestroform, being the pure oestrogenic hormone standardised in International Benzoate Units, possesses a specific action in the treatment of symptoms associated with the menopause.

Injections of Oestroform, 20,000 or 50,000 I.B.U. according to whether the condition is moderate or severe, should be administered twice weekly for three or four weeks until the symptoms have been brought under control.

As soon as alleviation of symptoms has been attained this dosage of Oestroform should be reduced, since the object of treatment is not to postpone the onset of the menopause indefinitely by the administration of large doses of oestrogenic hormone but merely to keep the distressing symptoms in abeyance and allow the patient to become adjusted gradually to the endocrine changes which are taking place.

Eventually it may be found that the oral administration of Oestroform tablets alone, say three of 1000 I.U. daily, may be sufficient to maintain the patient's hormonal level adequately. In certain cases at this stage a slight exacerbation of symptoms may be encountered from time to time due to a sudden variation in endocrine balance. This is only of short duration, and may be readily controlled by an injection of Oestroform.

It must be borne in mind that if the patient is still menstruating, Oestroform treatment should be confined to the first half of the intermenstrual interval, but when this has ceased treatment can, of course, be continuous.

"ALOCOL"

Colloidal Hydroxide of Aluminium

For Gastric or Duodenal Ulcer

IN view of the increasing adoption of intensive alkaline medication for gastric and duodenal ulceration, the selection of a suitable antacid agent is a matter of considerable importance to the general practitioner.

"Alocol" allows of antacid therapy in a particularly effective, safe and reliable form, and replaces with advantage mixtures composed of sodium bicarbonate, magnesia, bismuth, etc. It does not determine any unpleasant secondary reactions, even when taken in strong doses and over a long period of time.

The powerful antacid effect of "Alocol" is more mechanical than chemical in nature. It acts by adsorbing excess of hydrochloric acid, thus facilitating its elimination. It promptly relieves pain and being non-absorbable is free from toxic sequelae.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

Works: KING'S LANGLEY HERTFORDSHIRE.

M282

ALASIL

Safe Salicylate Therapy

THE popularity of acetyl-salicylic acid is undoubtedly due to the fact that it is one of the safest and most effective non-narcotic analgesics available. Too often, however, its use has been discarded by the physician on account of its tendency to irritate the stomach and because entirely pure preparations are not always available.

"Alasil" provides the beneficial therapeutic effects of pure acetyl-salicylic acid in such a form that it is acceptable even by disordered digestions. This tolerability is due to the fact that it combines calcium acetyl-salicylate—the least irritating salicylate compound—with "Alocol," a potent gastric sedative and antacid.

Since "Alasil" is better tolerated than acetyl-salicylic acid its use can be pushed or prolonged to a much greater extent than the latter. "Alasil" is, therefore, an analgesic, antipyretic, and anti-rheumatic which can be employed with complete confidence in all the many conditions in which such an agent is indicated.

A supply for clinical trial, with full descriptive literature, sent free on request.

TWO Useful Snake Venom Solutions

in the Therapy of Hæmorrhagic Conditions

Snake Venom Solution (MOCCASIN)

Lederle

Snake Venom Solution (MOCCASIN) acts to strengthen abnormally fragile vessel walls as in purpura, and also normal blood vessels as in some instances of bleeding due to a small submucous tumour of the uterus.

It has been used successfully in the treatment of functional uterine bleeding, persistent recurrent epistaxis, multiple hereditary telangiectasis and purpura hæmorrhagica, as well as in the preparation of patients for operative procedure in the presence of predisposition to excessive capillary bleeding, or in the post-operative treatment of such bleeding.

- A daily dose of 1 or 2 c.c. may be given over a considerable period of time without harm.

Fer-de-Lance Venom Solution

Lederle

Fer-de-Lance Venom Solution on account of its powerful coagulating property (500 times that of a solution of thromboplastin) is highly efficient in controlling surface bleeding (nasal bleeding, hæmorrhage following tonsillectomy and tooth extraction).

Persistent oral bleeding that has lasted several days, necessitating blood transfusion has been quickly and permanently stopped by the local use of the 1-5000 venom solution.

'PLASTULES' BRAND HÆMATINIC COMPOUND

IMPROVED IRON TONIC

Large doses of iron are no longer necessary for the successful treatment of hypochromic anæmia and debility. Independent investigations have proved that 'Plastules' yield rapid clinical response, equivalent to the results obtained from massive doses of other forms of iron. The average patient requires only three 'Plastules' Plain daily which obviates the unpleasant effects usually associated with massive iron feedings. Prescribe 'Plastules' for your patients and note the immediate results—appetite and colour return rapidly. Samples and literature on request.

'The Lancet' on **MOUSSEC**

"The wine has the appearance, composition and general properties of an ordinary dry French champagne. It is light and pleasant to the palate and has an agreeable aroma" ★ JULY 6, 1935 ★

● WHEN CONVALESCENTS NEED A *pick-me-up*

Moussec can be recommended with confidence. Moussec is sparkling wine produced from selected champagne grapes, fermented and matured in this country by the authentic champagne process. A special process of refinement gives to Moussec a purity and digestibility specially suited to invalids. It provides the valuable stimulus of champagne at an everyday price. The shilling "baby" bottle, which fills one champagne glass, provides daily Moussec in convenient form and keeps the wine keen and full of life until wanted for use. (Other bottlings up to 6/6).

O O O O O

MAGICO-MEDICAL TREATMENT OF SPRAINS, ACHES AND PAINS, WHICH HAS SURVIVED FROM PAGAN TIMES. The items employed are a "straining string" and some egg-shaped stones upon a flag stone in a Sligo churchyard. The patient, or a deputy, removes the "straining string" wound round the small rectangular stone block seen at the front left-hand corner of the flag stone, replacing it with another. He then takes each stone in succession, holds it between the thumb and second finger of the left hand, and, while turning it from left to right, repeats prayers—the substitute for pagan spells. The idea appears to be based on the belief that the spirits of the departed dwelt in stones, while knotting the string signified binding the demon driven out of the patient.

to St. Charles's (L.C.C.) Hospital*

AND

AMBROSE J. KING, M.B., F.R.C.S.

Chief Assistant Medical Officer, L.C.C. (Whitechapel) Clinic

In a preliminary report Anwyl-Davies (1937) described the results he had observed in a series of 157 cases of gonorrhoea in the male, treated with a serum prepared by Parke, Davis and Co., and described as a "specific antitoxin." The series included forty-two cases of acute uncomplicated gonorrhoea and 115 with complications, eighty-four of them acute, and his conclusions were: (a) that the results were distinctly encouraging; (b) that the "antitoxin" possessed specific therapeutic properties; (c) that clinical evidence suggested that both active and passive immunity were established; and (d) that the "antitoxin" seemed to offer considerable promise in the treatment of gonorrhoea.

The evidence supporting these conclusions was rather indefinite, as was pointed out by W. Lester (1937), but the claims made for the serum were so exceptional that we decided to try it. Our results in 129 male patients treated in these clinics agreed so completely in their lack of any evidence supporting the conclusions arrived at by Anwyl-Davies that we have combined them in one paper. These combined cases are shown in Table I.

TABLE I.—Combined Cases

Type of Case	St. Peter's	Whitechapel Clinic	St. Charles's	Totals
Uncomplicated:				
Acute... ..	48	16	3	67
Chronic ..	—	—	—	—
Complicated:				
Acute... ..	27	—	13	40
Chronic ..	22	—	—	22
Total ..	97	16	16	129

In this table, and also in the others, the term "uncomplicated" means with urethritis only, and "complicated" means with gonococcal infection of the urethral adnexa or other parts of the body. "Acute" means with infec-

tions of less than three months' duration at the time the patient came under our care, and "chronic" means with infections of more than three months' duration.

The serum used in our investigations was in two forms, described respectively as "unconcentrated antitoxin" and "concentrated antitoxin." According to the makers "unconcentrated antitoxin" is the original preparation made by a method practically identical with the Ferry procedure for the production and standardization of meningococcus antitoxin. "Concentrated antitoxin" is the original preparation after concentration by the Banzhaf method. This is said to remove excess of protein and leave the "antitoxin" in the pseudo-globulin fraction. Theoretically it is five times as potent as the unconcentrated preparation. In his report Anwyl-Davies describes results obtained with the use of both these preparations.

As indicated, the cases were treated in three series and the observations were made independently: those in St. Peter's Hospital, Whitechapel, which are presented first, by J. G.; those in the Whitechapel Clinic by E. T. B. and A. J. K.; and the last series, at St. Charles's Hospital, by A. H. H. At the end of the report we present a summary of our conclusions based on a combined study of all our results. We have not presented comparative findings in a series of controls, for reasons of space and because our results with this preparation have been so bad that the necessity for comparison does not arise.

St. Peter's Hospital Series

The results obtained from the use of the serum in ninety-seven cases at this hospital are shown in Table II. The ages ranged from 16 to 61 years, with an average of approximately 29. Those without complications were treated mostly as out-patients; all the complicated cases received in-patient treatment. All injections of the serum were given intramuscularly on consecutive days.

A HIGHLY SUSTAINING cereal food

Farex is a special reinforced cereal rich in protein and carbohydrate. It contains the protective vitamins A, B1, B2 and D, and is reinforced with calcium, iron and other tonic minerals. Moreover, Farex is palatable, easily digestible, non-irritant and non-laxative. It provides a stimulating, satisfying meal without cooking or special preparation—a great advantage in illness.

In pourer cartons ready to serve, 1/- and 1/9 (double quantity).

Boxes of 2 ampoules of 1 c. cm. containing 25 mg. per c. cm. ...	24/- per box.

The above prices subject to the usual professional discount.

Literature and clinical reports on request.

from four months to two years—average, twenty months. In the latter group the time since the onset varied from three days to six weeks—average, four weeks. The chief complications present on admission were arthritis in ten and epididymitis in six cases. Some of these patients had other complications, such as iritis and keratoderma blennorrhagica. The dosage was 2, 3, 5, and 10 c.cm. in twelve cases; four of 10 c.cm. in one case; 10, 15, and 20 c.cm. in one case; 5, 10, 15, and 20 c.cm. in one case; 1, 2, 5, 10, 20, and 20 c.cm. in one case; 1, 10, 10, 20, 10, 10, and 10 c.cm. in one case; and ten of 10 c.cm. in one case. Two patients received a second series of injections within a few days of the end of the first course. Added complications totalled five (31.2 per cent.), and consisted of iritis in one case, arthritis in one, epididymitis in two, and fibrositis in one.

(b) *Concentrated Serum* (6 Cases).—Four patients had had previous attacks of gonorrhoea. The chief complications present on admission were: arthritis in three cases, epididymitis in two, and iritis in one. The dosage was as follows: seven of 2 c.cm. in one case; six of 2 c.cm. in four cases; and 1, 2, and 3 c.cm. in one case.

The average period of in-patient stay for patients treated with unconcentrated serum was 40.5 days; with concentrated serum it was 40 days for patients with arthritis and 25.7 days for those with other complications. Again treatment with serum had to be supplemented later by ordinary methods.

Results.—The immediate clinical results indicated that unconcentrated serum had some adverse effect in eleven instances and did not retard recovery in five. The concentrated serum affected four cases adversely and produced no effect in two (both cases of epididymitis). In no instance was a patient discharged from hospital in less than nine days. In six of the ten patients with arthritis the joints had fully recovered on discharge from hospital. In four there was some limitation of movement. The following bacteriological and serological results refer only to the period of in-patient stay. In thirteen out of sixteen patients treated with unconcentrated serum the smears remained positive in nine and became negative in four. Of six patients treated with concentrated serum two showed gonococci in smears on discharge to out-patient treatment. The complement-fixation test in sixteen patients treated with unconcentrated serum remained positive in ten and became negative in five, while in the remaining case the serum was anti-complementary. In the patients treated with concentrated serum the complement-fixation test remained positive in four, became negative in one, and in one no test was carried out. In this series of twenty-two patients sixteen were traced after discharge. Of these, seven (31.8 per cent.) remain uncured after an observation period varying from eighteen months to two years. Nine patients defaulted (41.9 per cent.): three immediately, one at the second month, one at the third, one at the fourth, one at the sixth, one at the sixteenth, and one at the seventeenth. Thus in two years no instance of cure was recorded in this group.

REACTIONS

The majority of the patients treated with injections of serum complained of a variable amount of pain and stiffness at the sites of injection. Twenty-three of the total of ninety-seven had general reactions of one kind or another—namely, fifteen of seventy-six patients treated with unconcentrated and eight of twenty-one treated with concentrated serum. Ten of these suffered from pains in the head and at the injection site, combined with shivering, high fever, pain in the lower limbs, and malaise; the thirteen others developed urticarial rashes combined with a variable degree of headache, malaise, and pyrexia. Such reactions developed within a few minutes or hours of injections in some cases, but in others they were delayed for several days. Of the total of twenty-three patients who had reactions nine were under treatment for uncomplicated urethritis, ten for acute complications of

the disease, and four for chronic complications. The injection of adrenaline solution was not effective in controlling unpleasant symptoms in patients who had previously experienced reactions.

Whitechapel Clinic Series

In order to extend our observations with this preparation supplies of "unconcentrated antitoxin" were purchased through the ordinary commercial channels. Specimens of the serum were submitted to a series of complement-fixation tests with a gonococcal antigen in order to obtain evidence of the presence of gonococcal antibodies. These tests proved to be unsatisfactory owing to the anti-complementary nature of the serum, which was possibly due to the preservatives contained in the commercial product. It is understood that such tests do not form part of the manufacturers' method of standardizing this preparation. At the time these supplies were issued the daily dosage recommended was 3 to 5 c.cm. of the serum, given intramuscularly. It was hoped that, with the aid of this treatment, in favourable cases discharges would subside and gonococci disappear within the space of fourteen days. The serum reactions which resulted from this dosage were so severe that the medical representative of the manufacturers was consulted, and it was recommended that the initial dosage should be 0.5 to 1 c.cm., and that once the first reaction had occurred adrenaline solution should be injected half an hour before serum was given. This advice was followed, and accounts for the considerable variation in the dosage which these patients received (Table III).

The treatment was applied to sixteen male patients with acute uncomplicated gonorrhoea. These were unselected cases except in so far as it was necessary to stipulate the conditions of regular attendance and accessibility for close observation. All were treated as out-patients, and the average age was 25 years; the oldest being 37 and the youngest 18. Treatment was instituted in late June and early July of 1937, and most of these patients have remained under observation or treatment up to the time of writing in early December.

Observation was maintained by daily examination of the patients under treatment. Each day a record was made of the presence or absence of urethral discharge, of microscopical findings in the discharge, of the condition of the urine, of effects of the serum treatment, and of complications of the disease. It was planned to administer serum during the first fifteen days of treatment, withholding urethral irrigations during this time but giving irrigations from the end of the fifteenth day onwards, unless the condition of the patient warranted the cessation of all treatment. In some cases it was necessary to discontinue the injections before the end of the fifteen-day period owing to severe reactions, but in spite of this irrigations were withheld until the fifteen days had elapsed in all but one case. In others injections were continued beyond the fifteen-day limit in the hope of producing a delayed effect, and in these cases irrigations were withheld until the course of injections was completed.

All sixteen patients finally required irrigation treatment and received anterior and posterior urethral irrigation with 1 in 8,000 potassium permanganate solution once or twice daily according to the ability of the individual patient to attend. All the patients received the general treatment and advice which are routine in this clinic for those suffering from gonococcal infections, but no alkalis or other medicaments were given by mouth.

TABLE II.—Summary of Results from St. Peter's Hospital

Group	No. of Cases	Untoward Effects				Assessment of Results							
		Reactions		Complications		Excellent		Good		Fair		Bad

Total ..	97	23	24	17	18	—	—	—	—	15	16	82	84

The following is a detailed analysis of the cases summarized in Table II:

ACUTE UNCOMPLICATED GONORRHOEA

There were forty-eight cases in this group. Six were treated as in-patients and eight (19 per cent.) of the remainder had to be admitted to hospital later, either because of reactions which developed or because of the subsequent onset of complications (see below). The majority of cases came under observation within a few days of the appearance of the urethral discharge. Unconcentrated serum was given to forty-one patients and concentrated to the remaining seven. In forty-three cases the serum only was given at first, but in all of these it was necessary to continue with routine methods of urethral irrigations and alkalis by the mouth.

(a) *Unconcentrated Serum* (41 Cases).—This was given to forty out-patients and one in-patient. The dosage was 2, 3, 5, and 10 c.cm. on successive days in fourteen cases; and 10, 15, and 20 c.cm. in twenty-seven. In the group of fourteen patients two (14.2 per cent.) developed severe arthritis within a few days after completion of the course of injections and had to be admitted to hospital. In the group of twenty-seven patients one developed arthritis, one tenosynovitis, and two epididymitis (14.8 per cent.). The complication rate for the combined series was thus 14.6 per cent.

(b) *Concentrated Serum* (7 Cases).—This was used in the treatment of two out-patients and five in-patients. The amount given was 2, 3, and 5 c.cm. in two cases; six doses of 2 c.cm. in three cases; six of 1.5 c.cm. in one case; and 1, 1.5, 1.5, 2, 2, and 2 c.cm. in the remaining case. One patient (14.2 per cent.) developed epididymitis soon after completing the course of treatment.

Results.—The immediate favourable clinical, bacteriological, and serological results were negligible. No patient was cured in under four months. Of the forty-eight patients thirty-three subsequently attended the Whitechapel Clinic. Of these ten (21 per cent. of the total) were cured and twenty-two (46 per cent.) ceased to attend before cure. The criteria of cure were negative clinical examinations with repeated negative microscopical, cultural, and serological findings, and of the ten satisfying these requirements one did so at the fourth month, two at the fifth, three at the sixth, one at the eleventh, one at the fifteenth, one at the eighteenth, and one at the twenty-fourth. Of the twenty-two defaulters five had attended for one month, five for two months, one for three months, three for four months, two for five months, and six for from six to sixteen months. There are records of pathological tests for thirteen of these defaulters. In four cases some negative tests had been obtained at the time of default; in one case gonococci persisted in the urethral smear, and in eight the complement-fixation test was positive in the blood serum. One other patient is still attending at the Whitechapel Clinic after two years. One patient was transferred to another clinic after discharge from St. Peter's hospital.

ACUTE COMPLICATED GONORRHOEA

In this group of twenty-seven cases complications had developed within three months of the onset of the disease. The actual time interval varied from four and a half to six weeks. Nineteen were treated with unconcentrated and eight with concentrated serum. The frequency and distribution of complications at the outset were as follows: epididymitis in twenty, acute prostatitis in three, and arthritic complications (including inflammation of soft tissues) in four.

(a) *Unconcentrated Serum* (19 Cases).—This was given in four doses, of 2, 3, 5, and 10 c.cm. to fifteen patients; in three doses, of 10, 10, and 20 c.cm. to one patient; in four doses, of 5, 10, 15, and 20 c.cm. to two patients; and in six doses of 10 c.cm. to one patient. A patient who had received a total of 50 c.cm. of serum developed epididymitis in addition to his original complication. Another had 2, 3, and 10 c.cm. on consecutive days as an out-patient, and was admitted to hospital when he developed arthritis of one wrist, and tenosynovitis of the extensor tendons of the same hand. The added-complication rate was thus 10 per cent.

(b) *Concentrated Serum* (8 Cases).—With each dose a subcutaneous injection of 3 minims of 1 in 1,000 adrenaline hydrochloride was given on the supposition that it might prevent serum reactions. The dosages were: seven injections of 2 c.cm. to five patients; six of 2 c.cm. to one patient; six of 1.5 c.cm. to one patient; and six of 1 c.cm. followed by eight of 0.5 c.cm. to one patient. One patient was admitted for epididymitis occurring on the side opposite to that already treated. Another developed epididymitis and vesiculitis after six injections each of 2 c.cm. of serum. A third developed arthritis of the knees, tenosynovitis of one foot, and acute prostatitis after injections totalling 10 c.cm. of serum. The added-complication rate was thus 37.5 per cent.

Results.—The immediate clinical results indicated that the unconcentrated serum exerted an adverse effect in sixteen cases and did not impede recovery in three. The concentrated preparation appeared to have an adverse effect in four and to exert no effect in the same number. In no instance did any complication clear up more quickly after serum injections than by routine methods. In every case injections of serum had to be supplemented later by other methods of treatment.

The following bacteriological and serological results refer only to the period of stay in hospital, which averaged three weeks for this group. In seven patients treated with unconcentrated serum the smears remained positive in four and became negative in three. In six patients treated with concentrated serum the smears remained positive in three. For the remaining cases bacteriological records are not available. In the nineteen patients treated with unconcentrated serum the complement-fixation test remained positive in fourteen, became negative in three, and was unreadable in two. In all of the eight patients treated with concentrated serum the complement-fixation test remained positive. Of the twenty-seven patients in this series twenty-three have been followed up. Five of these are still attending the Whitechapel Clinic from twenty-one to twenty-four months after completing the course of serum injections. Six patients were cured (22 per cent.); two after six months, one after eight months, two after nine months, and one after eighteen months. There were twelve defaulters (44 per cent.): two within the first month, one at the second, one at the fourth, two at the sixth, two at the ninth, one at the fourteenth, one at the fifteenth, one at the eighteenth, and one at the nineteenth.

CHRONIC COMPLICATED GONORRHOEA

This group of twenty-two cases includes those patients with recent urethritis who had had one or more previous attacks of gonorrhoea and in whom relapse was suspected.

(a) *Unconcentrated Serum* (16 Cases).—Five patients were treated in the first attack and eleven in the second or later attacks. In the former group the time since the onset varied

It will be clear from this description that at any rate thirteen of these sixteen patients were really ill as the result of the treatment, and it must be regarded as a considerable credit to the resolution of this group of men that only three of them refused further injections in consequence of these symptoms. The two patients who suffered reactions of moderate severity had pyrexia, malaise, and muscle pains in less marked degree.

Injections of adrenaline did not appear to counteract or prevent reactions, but on the whole the effects were less persistent and less severe with smaller dosage of serum.

RESULTS

An attempt was made to assess the results of this treatment on the basis of the persistence of gonococci and urethral discharge, the spread of infection as judged by clinical findings, the duration of evidence of infection in specimens of urine, the effect on antibody content of the blood as measured by the complement-fixation test for gonorrhoea, the development of complications of the infection, and the application of tests for latency at the stage of clinical cure. At the beginning of treatment four patients had shown evidence that the infection had already extended to the posterior urethra. In the remaining twelve the signs suggested infection limited to the anterior urethra. All these developed signs of posterior urethritis while under treatment. Table IV summarizes the clinical and microscopical findings.

In none of these patients did the smears become negative or the discharge cease as the result of serum treatment alone. All required urethral irrigations. Six patients suffered a relapse of urethral discharge when the irrigations were discontinued after apparent clinical cure. Microscopical examination of these discharges showed gonococci in five cases. In four the symptoms and signs finally disappeared with urethral irrigations. In one patient (Case 2) it was necessary to use large doses of sulphanilamide after the gonococci had persisted for eighteen and a half weeks, a measure which resulted in disappearance of gonococci and urethral discharge within three days. The other patient (Case 3) has relapsed five times and still has gonococci after five months' treatment. In this case also it is proposed to use sulphanilamide.

As regards the effects on serum tests the most striking feature was the frequency with which specimens of sera were reported as "anti-complementary"—an unusual occurrence in the routine of clinic practice. Twenty-six such reports were received on specimens of blood from eight patients in this series, but the significance of this finding is not clear. The sera of three patients gave strongly positive ($++$ or $++$) reactions to the complement-fixation test after periods ranging from three to five weeks. Four others showed a positive (+) test in periods of from one week to four weeks. In five a weakly positive ($=$) reaction was recorded in the first few weeks. In four the tests remained negative throughout.

Complications of the Infection (5 Cases).—Four patients developed gonorrhoeal arthritis and rheumatism whilst under irrigation treatment subsequent to serum injections. One developed epididymitis on the left side, and one of the patients with arthritis had at the same time an acute inflammatory condition of Tyson's gland on the right side. Thus 31 per cent. of these patients developed acute complications of gonorrhoea.

END-RESULTS

The end-results are shown in Table IV, and may be summarized as follows. Three patients who have been under treatment from eighteen to twenty weeks have signs of persistent urethritis and so remain under treatment. One other patient proved entirely refractory to treatment

for eighteen and a half weeks until large doses of sulphanilamide were used, and has by this means reached the stage of clinical cure. Five defaulted after periods varying from four and a half to fourteen weeks; of these, four had persistent urethritis and one had reached the stage of clinical cure after fourteen weeks' treatment. One patient was admitted to hospital with gonorrhoeal arthritis and persistent urethritis after seven weeks of treatment and returned later with chronic prostatitis. The remaining five patients have reached the stage of clinical cure after treatment over a period of eight to eighteen weeks and are being submitted to tests of latency, which consist of complete clinical examination, including urethroscopy, prostatic smears, cultures of vesiculo-prostatic fluid, and complement-fixation tests of the blood serum. Up to the present undoubted evidence of latent gonococcal infection has been found in four of these. The results may be conveniently set out as in Table V:

St. Charles's Hospital Series

In this series injections of "unconcentrated gonococcus antitoxin" were administered to sixteen male patients, the average age of whom was 24 years, the maximum being 30 and the minimum 19. Fifteen were in-patients at St. Charles's Hospital, and were treated during the period July 6 to October 19, 1937. One, who received his injections at the Dreadnought Hospital, was subsequently transferred to St. Peter's Hospital, Covent Garden. We are indebted to Mr. P. P. Cole for details of this patient's previous treatment. None of the patients had previously had injections of serum. There were three cases of acute uncomplicated gonorrhoea, eight cases of acute gonococcal epididymitis (in one of which the symptoms of acute prostatitis were also present), and five cases of acute gonococcal arthritis. Smears of the urethral discharge were examined daily for leucocytes and organisms, and a record was kept of the condition of the first morning specimen of urine. The blood sera were tested at weekly intervals by the Wassermann and Kahn tests for syphilis and by the complement-fixation test for gonorrhoea.

The dosage of the serum is shown in Table VI. In some of the cases injections of a solution of adrenaline hydrochloride (1 in 1,000) were given with the serum; in others they were given fifteen minutes before or fifteen minutes after. The dosage of adrenaline hydrochloride corresponded in minims with the number of cubic centimetres of the serum. The time at which the adrenaline was given did not appear to influence the local or general reactions. No irrigation treatment was given during the course of injections, but the patients with acute arthritis had 5 per cent. iodine solution applied to the joints affected, and radiant heat was administered twice each day. Irrigations were withheld until at least four days had elapsed after cessation of serum treatment.

REACTIONS

Fourteen of the patients had severe local and general reactions and two developed only slight local reactions; seven had generalized urticarial eruptions. Most of these

The dosage of serum used in each case is shown in Table III, the figures in parentheses denoting the injections which were followed by reactions and the letter *a* indicating the administration of adrenaline solution. Subcutaneous injections of 1 to 5-minimis of adrenaline hydrochloride (1 in 1,000) solution were used according to the size of dose of serum; and in the large majority the doses of adrenaline were given half an hour before the serum was injected.

crippling nature, sufficient to cause interference with or cessation of the patient's work. The pain was accompanied by pronounced tenderness, and in seven cases there was widespread erythema of the skin of the affected buttock. The remaining six complained of varying degrees of stiffness and tenderness at the injection site.

General Effects.—The frequency of these is shown in Table III. Reactions which could be classed as severe occurred in thirteen patients, and in two they were moderately severe. The remaining patient had no symptoms attributable to the

16	8 "	8 weeks	8 "	Defaulted after 3 weeks. Unimproved.	

REACTIONS

Only one patient remained free from symptoms or signs attributable to the injections of serum; the other fifteen suffered from both local and general reactions. In most cases these occurred after the fifth to the seventh injection, and thereafter it was difficult or impossible to control them.

Local Effects.—Nine complained of pain at the site of injection in the buttock, and this pain was often of a severe and

injections. The severe effects included fever varying from 100.2° F. to 103.8° F., and this occurred in all thirteen patients. Almost all complained of severe headaches, malaise, "feverishness," and sweating. Skin eruptions appeared in eight patients, of whom three had generalized urticaria, three had a purpuric rash on the skin of the lower limbs, and two had papular erythematous rashes on the skin round the ankles and lower legs. Two had herpes of the lips. Generalized arthralgia occurred in nine cases; and in three there were joint effusions. Many of the patients complained of generalized muscle pains.

"GONOCOCCAL ANTITOXIN" IN GONORRHOEA

TABLE VII.—*St. Charles's Hospital Series: Findings during the Periods of Treatment and Observation*

Case	Period of Observation	Type of Case	Urine: Persistence of Haziness or Pus Threads	Subsequent History and Progress	Complications arising during Treatment
1	9 weeks	Acute right epididymitis	6½ weeks	Chronic urethritis. Defaulted in 9 weeks. Refused further treatment. Transferred unimproved to 3 months with epididymitis. Transferred unimproved. Finally improved with sulphamidamide and irrigations. Refused further treatment. Improved with sulphamidamide and irrigations. Improved, but relapsed, with gonococci. Improved with irrigations and sulphamidamide, then defaulted. Refused further treatment. Transferred, unimproved. Improved with sulphamidamide and irrigations. Finally improved with sulphamidamide and irrigations. Transferred unimproved. Finally cured with sulphamidamide.	Gonococcal arthritis both knees. Mono-articular arthritis became polyarticular. 14	7½ "	Acute uncomplicated urethritis	15 "		
15	15 "	"	"		
16	"	"	"		

Two others refused to continue with this form of treatment after five and seven injections respectively. Table VII indicates the findings in this series of patients during the periods of treatment and observation.

The assessment of results has been made with due regard to the effects observed during and immediately after the administration of the serum and also to the subsequent clinical course of the disease, on which the natural powers of immunity and the irrigation treatment used in all these cases must be held to have exerted considerable effect. Seven of the patients received sulphamidamide by mouth in addition to urethral irrigations before the infective process finally subsided. The results of the sixteen cases are summarized in Table VIII.

Summary of the Combined Series

The results obtained in the combined series of 129 cases treated with "gonococcal antitoxin" at the three clinics are set out in Table IX.

TABLE IX.—*Results in the Combined Series*

Series	No. of Cases	Untoward Effects		Assessment of Results			
		Reactions	Complications	Excellent	Good	Fair	Bad
		No.	%	No.	%	No.	%
St. Peter's ..	97	23	17	—	—	15	82
Whitechapel ..	16	15	5	—	—	—	16
St. Charles's ..	16	16	6	—	—	1	13
Total ..	129	54(41%)	23(21%)	—	—	16(13%)	111(87%)

The contrast between these combined results and those reported by Anwyl-Davies will be clear from comparison between Table IX and Table X, in which his results are summarized.

TABLE X.—*Percentages of Results Given in Preliminary Report (Anwyl-Davies, 1937)*

Excellent	Good	Fair	Bad
49.6	25.9	14.8	5.9

In a personal communication Dr. V. E. Lloyd, director of the venereal disease clinic at Guy's Hospital, states that serum was given to three male patients, but the reactions were in every case so severe that it was not considered justifiable to adopt this method of therapy with any further patients.

The main facts which emerge from our combined experience are these:

- With this "antitoxin" a disquietingly high proportion of patients developed reactions so severe as to cause interference with or absence from work.
- An abnormally high percentage of out-patients had to be admitted to hospital during and subsequent to serum treatment on account of reactions and complications.
- The serum not only does not prevent complications of the infection but it appears to render patients more prone to them.
- The administration of this serum to patients suffering from metastatic lesions appeared to encourage rather than to prevent extension to other sites.
- Favourable results were not obtained by serum alone but only after the subsequent adoption of routine methods. Even then good results were delayed beyond the usual period in which they are obtained in patients treated without serum. We take this to indicate that the serum reduces or temporarily destroys the patient's immunity. This is the probable explanation of the high complication rate.
- The cases which, after the cessation of serum therapy, responded most favourably were those treated with sulphamidamide. But here, again, that agent did not act any more rapidly than it does in patients treated without serum.
- Certain anomalous results in respect of the Wassermann and Kahn tests occurred in non-syphilitic patients during the serum therapy. This finding is of manifest importance to those who use this serum in the treatment of gonorrhoea.

occurred after the sixth injection, regardless of the dosage. One appeared after the third and another was delayed until fourteen days after the last injection. In thirteen patients there was severe pain, swelling, and tenderness in the buttocks; in three of them a local erythematous blush was observed, and in these areas there were numerous purpuric spots which took several days to disappear. One other patient showed purpuric lesions in both antecubital fossae. It seemed as if the serum

* At the outset of the investigation an initial dose of 3 to 5 c.cm. was recommended by the manufacturers. Severe reactions resulted, and it was then advised that the dosage should be reduced.

contained a substance which damaged the vessel walls and increased their permeability. From one patient (Case 3) a fading purpuric lesion was excised. On microscopical examination no appreciable change in the epidermis was found. The superficial blood vessels in the corium were slightly dilated and had a lymphatic cell infiltration around them, and here and there were a few eosinophils and some extravasated corpuscles. In fact, this was a typical section of skin purpura. An itchy papular eruption on the forearms was seen in two patients; and one of them, who also had a generalized giant urticaria, subsequently developed a nummular eczema.

In many of the patients the constitutional disturbance was pronounced. The temperature rose as high as 103° F. It was surprising that the fever produced by the injections did not have the usual beneficial effect on the course of the disease, as the results obtained will show. One patient had a severe asthmatic attack on two occasions following injections of serum, and each time there was almost instantaneous relief after a subcutaneous injection of 3 minims of adrenaline hydrochloride. There was no history of previous asthmatic attacks.

Two patients (Cases 7 and 9) complained of nausea during the treatment, and one (Case 9) vomited at night after the sixth injection and each night subsequently. This continued for three nights after his last, or ninth, injection.

RESULTS

The microscopical findings in the urethral discharges gave no evidence that benefit had been derived from the injections; and at the end of the period of treatment with serum gonococci were found in smears of the urethral discharges from all the patients treated. One patient (Case 7), who was admitted with arthritis of a week's

duration, had received a course of urethral irrigations elsewhere. No gonococci were found in the urethral smears or in the urine at the first examination, but after four injections of serum large numbers of gonococci appeared in the daily urethral smears until irrigation treatment was recommenced.

The clinical results were all unsatisfactory. Urethral discharges in the majority of cases became more profuse during treatment. There was no indication that the condition of the joints of those suffering from acute arthritis was improved, and in three patients the joint pains were increased for several hours after each dose of serum. The injections seemed to have no influence in preventing other joints from becoming infected, and in four out of the five patients with this complication further joints became involved. One patient (Case 5) who was suffering from acute arthritis of the right knee with a metastatic gonococcal conjunctivitis developed, after three injections each of 5 c.cm. of serum, acute infection of the left temporo-mandibular joint, right elbow, left wrist, and the proximal interphalangeal joints of the fourth and fifth fingers of the right hand. Another patient (Case 7) was suffering from acute arthritis of the metatarsophalangeal joint and the first interphalangeal joint of the left big toe; after three injections of 1 c.cm. of serum he also developed acute arthritis of the right knee and the right ankle. Another (Case 9), with acute arthritis of the interphalangeal and metatarsophalangeal joints of the left foot and the right midtarsal joint, developed acute arthritis of the right knee and a bursitis over the right ischial tuberosity after three injections of the serum, each of 3 c.cm. A fourth (Case 13), who was suffering from acute arthritis of the right hip and right midtarsal joints, also developed acute arthritis of the left knee after he had had three injections, each of 2 c.cm. of serum. One patient (Case 3), admitted with acute prostatitis and left epididymitis, developed arthritis of both knees after the ninth injection of 3 c.cm. of serum.

It will be noted that extension of the infection to other joints during serum treatment occurred in 80 per cent. of the patients suffering from arthritis. On reference to the case records of eighty other patients with gonococcal arthritis treated by orthodox methods at St. Charles's Hospital and elsewhere, it was found that in only 11.25 per cent. had the metastatic involvement extended to other joints.

LABORATORY TESTS

Study of the literature has revealed no references to the possible effects of injections of serum on Wassermann and Kahn reactions in the blood serum. As already stated, these tests were carried out at weekly intervals in fifteen cases, and in nine of the patients one or other test became positive during the period of administration of serum or shortly afterwards. In eight of these nine patients there was no correlation between the positive findings in Wassermann and Kahn tests. In all but one case both tests had become negative without antisyphilitic treatment before the end of the observation period. In the other case the Kahn reaction was positive at the end of this period, but the Wassermann reaction remained completely negative.

When the patients first came under observation the gonococcal complement-fixation test was positive or weakly positive in seven and completely negative in eight cases. Of the latter group, six subsequently developed positive reactions. The serum appeared to exercise no influence on the strength of the complement-fixation test in the seven who originally had positive reactions. The results of these tests were often reported as "anti-complementary."

One patient (Case 10) refused further treatment after two injections and demanded his discharge from hospital.

HUMAN INFECTION WITH ACTINOMYCES CAPRAE

sypilis. No enlarged glands were observed, and the thoracic organs were normal. The spleen was enlarged to half an inch below the level of the umbilicus and as far as the mid-line, while the liver edge was palpable below the costal margin. The urine was clear, natural in colour, and contained no bile, but urobilin was present in small amount. There was no deposit. The blood count was as follows: red cells, 4,230,000 per c.mm.; haemoglobin, 64 per cent.; colour index, 0.7; white cells, 9,500. The differential count showed: polymorphs, 28 per cent.; lymphocytes, 62 per cent.; monocytes, 10 per cent. The red blood corpuscles were small, there was marked punctate basophilia and polychromasia; platelets were present but not abundant. The icteric index was 32 units. The Wassermann and sigma reactions were negative. Fragility of the red cells began at 0.6 per cent. saline and was complete at 0.32 per cent. A normal control done at the same time began at 0.32 per cent. and was complete at 0.28 per cent. Under observation the spleen became very slightly smaller and the jaundice less marked.

Operation.—This was performed by one of us (R. H. R.-I.) on July 6, 1936, under gas-and-oxygen anaesthesia given by Drs. Duigan and Alsop. The abdomen was opened by a V-shaped incision; the spleen was very large, and was adherent to the stomach and kidney, the hilum being closely involved with the tail of the pancreas. The adhesions were divided, the pedicle ligatured and divided, and the spleen removed without loss of blood. The wound was closed and strengthened with silk-worm-gut sutures. The wound healed well and the jaundice disappeared after the third day. The patient was discharged on August 1, 1936.

In October, 1937, he was a well-nourished boy without jaundice, and on examination his blood count was as follows: red cells, 5,020,000 per c.mm.; haemoglobin, 94 per cent.; colour index, 0.94; white cells, 18,800 per c.mm.; reticulocytes, 0.2 per cent. The differential count gave the following percentages: eosinophils, 4; metamyelocytes, 0.5; neutrophils, 62.5; lymphocytes, 29.5; monocytes, 3.5. The film showed slight anisocytosis and poikilocytosis; the corpuscles were small, but no polychromasia or punctate basophilia was present. The fragility was less than before the operation, but was not normal.

Description of the Spleens

Case I.—The organ was about five times the normal size and weighed 1,314 grammes. It had shrunk considerably from loss of blood. The substance was firm and was deep red on section; the capsule was slightly thickened. Malpighian bodies were difficult to identify, but trabeculae were easily seen, and some of them showed reddish opaque points of the siderotic or Gandy-Gamna nodule. Histologically several of these showed thick mycelial fibres, some undergoing calcification. In a few instances these fibres appeared to be in process of absorption. Eosinophils were present everywhere in the splenic tissue. It was possible to excise thirty-six of these nodules under aseptic precautions. They were ground up with a little broth in a sterile mortar and inoculated upon twenty-four whooping-cough agar plates and a dozen tubes of the same medium. After a week one plate suggested a growth of actinomycetes, and after four weeks the greater part of the surface was spread over with an actinomycetes growth, salmon pink in colour and adherent to the underlying medium. The plates otherwise were sterile except for a few colonies derived from air contaminations.

Case II.—The organ preserved its shape and was three times the normal size—8 in. by 4 in. by 3 in. The capsule was turgid but not thickened. Numerous minute buff-coloured siderotic (Gandy-Gamna) nodules could be identified in each cross-section of the spleen. The pulp was congested and moderately firm. Malpighian bodies could be distinguished only with difficulty. As in Case I

the procedure was adopted of grinding up a number of excised nodules in broth. Altogether the inoculations were made on fifty-one tubes of various media, solid and liquid, and eleven whooping-cough plates. Except for a few obvious contaminations these proved sterile, observed during a period of several months.

Description of the Organism

Subculture on broth after one week's incubation at 37° C. showed small flocculent colonies at the bottom of the tube. On the surface of the broth was a pellicle composed of small spherical colonies covered with a layer of white aerial mycelium. The appearance so strikingly resembled that of a strain of *Actinomyces caprae* obtained from the national collection of type cultures that parallel series of cultures of both organisms were made on whooping-cough agar (as used in the Serum Institute at Copenhagen), litmus milk. Dorset's egg medium, and blood agar, on which *Actinomyces caprae* shows its most characteristic features. Both organisms presented identical appearances, as follows: on whooping-cough agar, after seven days' incubation at 37° C., there were numerous orange colonies which had become confluent. The surface was much heaped up, and was covered by a layer of white aerial mycelium. After three weeks the colonies were heaped up still more and the aerial mycelium had turned salmon pink. On litmus milk, after one week at 37° C., the growth on the surface was pale orange. After a month the milk was peptonized. On blood agar, after a week's incubation at 37° C., there appeared small cream-coloured colonies covered by a thick layer of white aerial mycelium. No haemolysis occurred. After one month the colonies had extended so as to produce a thin margin, but there was no haemolysis. On Dorset's egg medium, after a week's incubation at 37° C., there were irregular pimple-like orange colonies covered with a thick layer of aerial mycelium.

Morphologically the strain belongs to Group IIa of Orskov's classification in that after twelve hours at 37° C. the mycelium breaks up into rods and cocci of various sizes and there is early formation of aerial mycelium. The breaking up of the threads begins with the appearance of fine transverse division lines, and the segments which ultimately form are displaced at different angles from one another. The same displacement occurs in the aerial mycelium.

Staining Properties.—The organism is Gram-positive (Claudius's method), and stains readily with haematoxylin, carbol fuchsin, and malachite-green. Parts of the mycelium are acid-fast.

Pathogenicity.—*Actinomyces caprae* is pathogenic for rabbits and guinea-pigs, and Dr. R. L. Vollum kindly undertook to make injections of both strains into these animals. Two guinea-pigs and two rabbits were injected subcutaneously. All the animals killed after three weeks showed subcutaneous abscesses, the strain from Case I producing slightly larger lesions than *Actinomyces caprae*. In all abscesses colonies of actinomycetes were found on microscopic section.

Discussion

We are unable to explain the occurrence of *Actinomyces caprae* in the cultures from the excised spleen of Case I except as a pathogenic agent in intimate relation to the splenic tissue. It is inconceivable that it could have been an accidental invasion or contamination. The reason why only one plate was infected is one that concerns the isolation of actinomycetes in known cases of this infection:

(h) The results obtained in these series were most unsatisfactory and were at complete variance with those reported in the preliminary account of the use of this preparation.

Conclusions

1. The serum described as "gonococcal antitoxin" appears to have no specific anti-gonococcal effect.

2. It appears to delay the development of the active immunity essential to recovery from gonorrhoea without substituting any compensatory passive immunity.

3. Its use in gonorrhoea is inadvisable on account of its lack of therapeutic value, its serious side-effects, its frequent interference with recovery, and possibly also the risk of its rendering patients liable to suffer from serious allergic reactions in the event of their requiring at some future date treatment with antitoxic sera for other bacterial infections.

[In a communication published after this paper was written Anwyl-Davies (*St. Thomas's Hospital Reports*, 1937, 2, 67) states that since his first report appeared many additional patients have been treated with an improved unconcentrated antitoxin. The precise number of patients is not stated, but the results claimed are: "excellent" and "good" together, 78 per cent.; "fair," 18 per cent.; "bad," 4 per cent.; with no clinical relapses to date.]

The London County Council accepts no responsibility for the opinions or conclusions expressed in this article.

The subject from whom this organism was isolated was one of two cases (Case I) of acholuric jaundice in a brother and sister. The following are the clinical histories.

Case I

A girl aged 14 was admitted to hospital on May 22, 1936, with a diagnosis of acholuric jaundice and splenomegaly. Her father was alive and well, with no history of jaundice and no evidence of jaundice or splenomegaly when he was examined on June 6, 1936. Her mother was healthy and active and without jaundice. One brother (Case II) had jaundice and splenomegaly. Four other children were alive and well.

Clinical History.—The patient was healthy at birth, but developed jaundice, which persisted. She had measles when a small child, and while in hospital in 1930 she contracted diphtheria. She was sent to the fever hospital and recovered without complication. The patient suffered from attacks of abdominal pain, mainly on the left side, associated with vomiting and a cold in the head. These attacks occurred every two or three months. The yellow colour increased with the attacks of vomiting. The motions had been normal in colour and the urine had not been dark.

Examination.—The patient was seen to have an adenoid facies and a marked icteric tinge of the skin and conjunctivae. There were petechial haemorrhages on the arms and trunk. Her weight was 74 lb. (the average for 11½ years). The right tonsil was larger than the left, and her teeth were normal. No abnormality was found in the heart and lungs. The spleen was greatly enlarged, and extended to one inch below and two inches to the right of the umbilicus. It was firm and not tender. The liver was slightly enlarged. There were no enlarged lymph glands. The urine was dark; bile was not present, but the test for urobilin was positive, and albumin was found. The deposit showed numerous cellular casts but no organisms. A blood count showed: red cells, 2,280,000 per c.mm.; haemoglobin, 46 per cent.; colour index, 1.0; white cells, 7,200 per c.mm. Differential count: polymorphs, 64 per cent.; lymphocytes, 22 per cent.; mononuclears, 6 per cent.; eosinophils, 8 per cent. All the red corpuscles were small, and two nucleated red cells were seen. There was some anisocytosis, poikilocytosis, and punctate basophilia, and platelets were present. The van den Bergh reaction (indirect) was positive. The icteric index was 55, the bleeding time two and a half minutes, and the coagulation time eight minutes. In the test for fragility haemolysis began at 0.66 and was complete at 0.54 per cent. (a normal control began at 0.32 and was complete at 0.28 per cent.). The sigma reaction was negative. Blood group, IV. An x-ray report on the hands showed no signs of rickets, but there was slight osteoporosis of the metacarpals. The patient was kept under observation in hospital for a month and was given large doses of potassium iodide, but no change occurred in the size of the spleen.

Operation.—This was performed by one of us (R. H. R.-I.) under gas-and-oxygen anaesthesia (Dr. Duigan). The spleen was exposed by a V-shaped incision. The head of the pancreas was found to be closely adherent to the pedicle of the spleen. There were some adhesions, which were ligatured, between the spleen and the stomach and kidney. The pedicle was carefully divided and the spleen removed without any excess of bleeding. The wound was closed with silkworm-gut sutures to the skin surface.

Progress.—The jaundice disappeared within a week and recovery was uneventful. The patient was discharged to a convalescent home on July 27, 1936. In October, 1937, she had grown and put on weight, and was more normal in appearance, without jaundice, though the tonsils were very large. A blood count showed: red cells, 4,990,000 per c.mm.; haemoglobin, 90 per cent.; colour index, 0.9; white cells, 17,000; reticulocytes, 0.07 per cent. The differential percentages were: eosinophils, 4.5; metamyelocytes, 1.5; neutrophils, 55.5; large lymphocytes, 2; small lymphocytes, 35.5; monocytes, 2.5. In the film there was slight anisocytosis, and most of the red corpuscles appeared smaller than normal. Poikilocytosis was slight, and no polychromasia, punctate basophilia, or nucleated forms were present. The fragility began at 0.4 per cent, and was complete at 0.32 per cent.—less than before operation and only slightly above a normal control.

Case II

A boy aged 7, brother of Case I, was admitted to hospital on May 22, 1936, with a diagnosis of acholuric jaundice and splenomegaly. He had been a full-time normal baby, weighing 8 lb., and was breast-fed. Jaundice persisted from birth, and he also had measles when 4 years old. He was always tired. The jaundice varied somewhat, and he had frequent attacks of sickness with pain in the abdomen, sometimes being constipated. The stools were normal in colour.

Examination.—He had an adenoid facies, with an appearance of having a large head; measurement, however, gave a circumference of 20½ inches (normal for age). His weight was 49½ lb. His intelligence was rather below the average. There was general slight jaundice, which included the conjunctivae. Petechial haemorrhages appeared on arms, legs, abdomen, and chest. The left tonsil was larger than the right. The upper and lower central incisors were notched along the cutting edge, but there was no suggestion of

FAMILIAL CLUBBING OF FINGERS AND TOES

MARCH 19, 1938

In 1902 Newton and Mercellis published the record of a Hungarian family in which a man aged 33, his four children, his brother, and his paternal grandfather had clubbing of the fingers and toes. The patient's father, who had been asthmatic, had died of cholera at the age of 36, and was said to have had normal fingers. On the paternal side the family had suffered from cough and shortness of breath, and had as a rule died of some lung complaint. The patient, who at this time was suffering from an indolent axillary abscess, said that his fingers and toes had been clubbed since birth. He had contracted a venereal sore at the age of 31, and had been refused admission to the Army because of a "weak chest"; he had a chronic morning cough, otherwise his health was good. Three of his four children had died in infancy, but all were said to be affected. The remaining child, a girl aged 4, was found to have clubbed fingers and toes, and also "acute endocarditis." In 1911 von Eiselsberg described a man aged 30 with clubbed fingers and toes, which he had had "since birth"; a grandfather, an uncle, and a sister were said to be similarly affected. Nothing was said about the man's parents or other relatives.

The following report of a case admitted to St. James's Hospital, Leeds, shows the condition to have been present in three successive generations.

Case Record

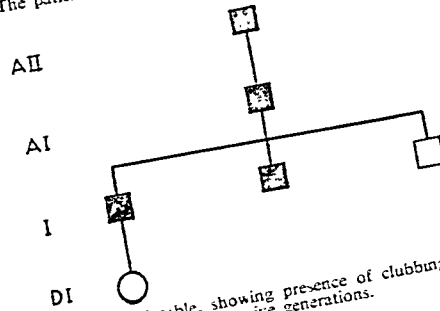

A man (I, 2 in the pedigree) aged 42, a piano-tuner, was admitted on April 10, 1937, suffering from a left hemiplegia, which had come on suddenly the previous day. Before this he had enjoyed good health, apart from occasional attacks of pain and swelling in his right great toe, which he had been told was gout, and several momentary bouts of dizziness during the month preceding the stroke. On examination it was found that his heart was enlarged, the apex beat was $4\frac{1}{2}$ inches from the mid-sternal line in the fifth left interspace, his blood pressure was 230/150 mm. Hg, the Wassermann reaction was negative, and the urine was normal. Apart from the degree of clubbing of the fingers and toes. Questioned regarding these he said that they had started to enlarge at the age of 21, and had quickly attained their present size, which merited the epithet "drumstick"; the nails had a livid tinge, and were curved like an inverted watch-glass. A radiograph of the chest showed left ventricular hypertrophy and normal lung fields: radiography showed no changes in the bones of the hands. The patient was aware of his abnormality, and said that his elder brother and his father had the same condition. His brother (I, 1 in the pedigree), aged 53, was next interviewed. He had lost three fingers of one hand in an accident, but the remaining fingers and his toes showed the same degree of clubbing as his brother's. He said that he had had the condition as long as he could remember. His health has always been good apart from recent slight winter cough, and he has been no physical signs of disease at present. The third brother (I, 3) was not seen, but was said to be unaffected; he has been out of touch with the family for twenty years. The father (AI) died at an advanced age of cancer of the throat; nothing of his sons agreed that he had clubbed fingers, but a battered photograph of a family group showed quite plainly that both he and the father (AI) were affected. The patient's niece (DI) aged 29, was seen and was found to be normal.

This is the second family to be described in which the deformity runs directly through three generations. In the case of a hereditary condition this is sufficient to show that the abnormality is probably inherited as a simple Mendelian dominant: all the previously reported instances conform to this hypothesis, with the exception of those which I have called anomalous. In the family described by Newton and Mercellis the patient said that his paternal grandfather was affected, but that his father was not.

Assuming that he was not mistaken, it is possible that the father had died before the anomaly appeared, as in one of the cases that I have described the condition was not evident until the age of 21, and in one of West's cases not until after 50, though this was not shown to be familial. Alternatively the clubbing may have arisen out of the lung

The patient's hands, showing the degree of clubbing of the fingers.

Genealogical table, showing presence of clubbing in three successive generations.

diseases to which this family was subject, although this seems unlikely. In von Eiselsberg's report no information is given except the bare facts abstracted above, so it does not afford enough material for discussion; but the argument that the patient's father or mother may have died before their fingers became altered applies here also.

Conclusion

As in most cases the normal members of the families have not been recorded it is impossible to compare their numbers with the numbers of affected persons; in the fully reported families the ratio of affected to unaffected persons is 15:10, which is as near to the 1:1 ratio of Mendelian dominants as one can expect with such a small number. At all events it can be said that extreme clubbing of the fingers and toes may occur in the absence of organic disease, and that the probability is that in some of these cases the condition is inherited as a simple Mendelian dominant.

My thanks are due to Dr. H. G. Garland and Dr. S. I. Hartfall for their advice and criticism.

many specimens have to be taken and but few are positive. The number of cases, however (now amounting to thirteen), from which actinomyces has been obtained from the excised spleen or blood in acholuric jaundice, splenic anaemia, and Banti's disease makes it probable that the present organism bears an aetiological relation to the disease.

This is the first occasion on which a known pathogenic species of actinomyces has been isolated from cases of jaundice. It also appears to be the first occasion on which *Actinomyces caprae* has been found in a human case. *Actinomyces caprae* was first isolated from the lung of a goat by Silberschmidt (1899), Galli-Valerio (1912) obtained it from the same source.

An attempt has been made to identify agglutinin to *Actinomyces caprae* in the blood of the patient. The organism is particularly difficult to emulsify. A thin emulsion, however, made by continual shaking of a twenty-four-hour broth culture showed no agglutination as tested against the serum of Case I. The serum of Case I added to a broth culture of the organism increased the rate of growth and brought out more prominently the characteristic colour of the organism as compared with six normal control sera. Again, the siderotic nodules in the spleen on first exposure were a buff colour, but on being incubated in culture tubes under aerobic conditions they assumed the same tint as an old culture on agar.

The patients come of peasant stock and were born in a cottage which had been part of an old farm; it is said to have been very insanitary, and has since been pulled down. A neighbour used to keep ten to twelve goats, and occasionally these used to stray into the garden of the cottage occupied by the patients. There is no history of their having drunk goats' milk.

Summary

Two cases of acholuric jaundice are described in which splenectomy had the effect of completely relieving the jaundice, restoring the haemoglobin and number of red corpuscles to normal, and diminishing the fragility. From the spleen of one of these patients an organism was isolated which gave the characteristic reactions of *Actinomyces caprae*. It is concluded that this organism was an essential pathogenic agent in the production of the disease.

[Note.—Since the above was written a sister of the patients (aged 17), referred to in the text as normal, has come under observation with jaundice, splenomegaly, and a haemoclastic crisis.]

On June 16 King Gustaf V of Sweden will celebrate his eightieth birthday, and a national subscription has been opened to celebrate the occasion. In accordance with the King's own desire the funds collected will be used for research into and for combating infantile paralysis and rheumatic diseases. Subscription lists have been issued throughout the country and also in Swedish Legations and Consulates abroad, thus giving an opportunity to Swedes, whether at home or in foreign countries, to contribute. A similar appeal on the occasion of King Gustaf's seventieth birthday brought in the splendid total of just over 5 million kronor (£275,000 at par). The fund on that occasion was earmarked for cancer research and the establishment of cancer clinics. Large sums from this fund have been spent on purchase of radium, and some of the projected clinics have already been opened.

FAMILIAL CLUBBING OF THE FINGERS AND TOES

BY

D. R. SEATON, M.A., M.B.

House-physician, St. James's Hospital, Leeds

Although it is not uncommon to find clubbing of the fingers in the absence of apparent cause (I have seen two instances during the past year), reports of such cases are infrequent, but they have been described by Mangelsdorf (1885), West (1897), and Lewy (1921). Decloux and Lippmann (1902) recorded the occurrence of clubbed fingers and toes in a man aged 55 and in his sister aged 30; there were sixteen other brothers and sisters, who were said to be unaffected, as were their parents and the man's children. None of these was seen. The affected pair said that the condition had been present since birth; neither had any pulmonary or cardiac disease. Weber (1919) put on record the cases of twin brothers aged 25 with clubbed fingers; another brother, aged 30, was not seen, but was said to be likewise affected. All were quite healthy.

Cases occurring in Two Successive Generations

Cases occurring in two successive generations have been recorded in six instances. Fraentzel (1888) described a healthy man showing "drumstick" fingers, his father and his sister having the same condition. Freytag (1891), in his monograph on clubbed fingers, mentioned two instances of father and son being affected in the absence of disease. Weber (1919) found clubbing of the fingers and toes of a man aged 25 and his father; three brothers and a sister had a like condition. Crouzon and Gutmann (1931) reported clubbed fingers in a healthy man aged 30; a radiograph of his hands showed normal bones. The father had been similarly affected, but had suffered from a chronic "broncho-pulmonary" condition. Kayne (1933) published a record of a family in which two brothers, a sister, and the father had clubbed fingers and slightly clubbed toes; the mother and four sisters were normal. The patient's Wassermann reaction was negative, as was a radiograph of his chest. Radiography of his hands showed only slight splaying of the terminal phalanges. In the same year Ragins and Freilich (1933) described a family in which a man, his sister, father, and a paternal uncle all had clubbed fingers and toes.

Witherspoon (1936) reviewed the articles on the subject and reported a negro family in which four brothers and their father had clubbed fingers and toes. One of the brothers had two children, aged 2 months and 17 months, who were found to have pronounced thickening of the volar pads of the fingers and thumbs, but no true clubbing. A maternal half-brother was said to be affected. The mother and four sisters had normal fingers and toes. Wassermann reactions were negative, and radiographs of the chest were normal in all cases examined. Neurath (1932) described four families in which clubbing of the thumbs and big toes was inherited as a simple Mendelian dominant. The clubbing in these cases was due to a bony malformation of the terminal phalanges, and was a special variety of brachyphalangia; for this reason it is not comparable with the present series.

Anomalous Inheritance

In the foregoing reports the inheritance is straightforward, from father to son; but there are two families described in which the inheritance is apparently anomalous.

T.A.O.=Thrombo-angiitis obliterans. R.P.A.=Right popliteal artery. L.P.A.=Left popliteal artery. A.S.O.=Arteriosclerosis obliterans. L.F.A.=Left femoral artery. R.F.A.=Right femoral artery. A=Relief of nocturnal pain. B=Healing of gangrene. C=Increased walking capacity. D=Increased skin temperature.

Results

Recent cases still under treatment have not been included in the series of thirteen here reported. It will be noted that improvement occurred in all those treated with intermittent venous occlusion with the exception of Case 10. Nocturnal pain was present in six patients, including Case 10, and invariably relief of pain was obtained, in some instances within a few hours of starting treatment. It is interesting to note that although nocturnal pain was completely relieved in Case 10 the condition did not further respond to treatment.

Intermittent claudication was present in all but three patients (Cases 8, 11, and 12), one of whom was unable to walk because of diabetic skin lesions, another because of coronary disease, and the third because of recent amputation of the other leg. In the remaining ten patients, with the exception of Cases 9 and 10, there was a very satisfactory increase in walking capacity, in one case even to the extent of allowing the patient to take part in deer-stalking. Three patients (Cases 2, 5, and 7) were completely incapacitated when first seen, and are now able to work.

Six patients (Cases 3, 5, 8, 10, 11, and 12) showed degrees of gangrene varying from localized areas in Cases 3 and 5 to more extensive lesions. Thus Cases 8 and 10 had extensive gangrene of the left heel; Case 11 had lost the other leg through gangrene a month previously and showed a gangrenous area on the remaining big toe; and in Case 12 there was gangrene of the first and second toes. In all these cases treatment was successful in healing the gangrenous area without loss of tissue except in Case 10, where despite intensive methods healing could not be promoted and amputation was advised.

Discussion

It will be seen that apart from the clinical improvement the skin temperature has increased in practically every case. All cases were examined under the same constant temperature conditions before and after treatment. Sympathetic inhibition was induced, and the figures quoted represent the rise of temperature following treatment.

With the exception of Cases 4, 6, and 9, all belong to Group II—that is, those with a poor collateral circulation. In this group improvement can only be effected by assisting the formation of an efficient collateral circulation. It is therefore to be presumed that the poorer the initial collateral circulation the more dramatic will be the results of treatment, provided always that the condition is not so far advanced that the patient is no longer susceptible to treatment of any kind, as in Case 10. On the other hand, as might be expected, it has been our experience that certain of the cases in Group III with an initially very good collateral circulation would be unlikely to benefit from a form of treatment designed to develop a better collateral circulation. We therefore consider that in cases of this type treatment by intermittent venous occlusion is not indicated; arteriography with thorotrast, however, may be carried out to establish the nature and site of the local obstruction. Case 9 is an example of this type where intermittent venous occlusion failed to improve the already satisfactory collateral circulation. Arteriography revealed a localized block in the superficial femoral artery, and the excision of this segment of the vessel was followed by the complete relief of symptoms. It may be possible by means of intermittent venous occlusion so to improve the collateral circulation in certain cases of Group II that they may be amenable to similar treatment if symptoms are still present. We find that the response to treatment is better in the younger patients, who are mostly suffering from thrombo-angiitis obliterans, due doubtless to the greater capacity of their smaller collateral vessels to dilate.

While the results of treatment have been satisfactory, we have been unable to observe any actual increase in skin blood flow when specially designed foot calorimeters have been employed. Allan and McKechnie (1937), using a thermo-electric method, were unable to demonstrate any rise in skin temperature. However, it must be realized that both these methods indicate only the skin blood flow. Studies are being continued with particular reference to procedures better calculated to record muscular blood flow.

It is the consensus of opinion that in thrombo-angiitis obliterans any form of treatment will in large measure

TREATMENT OF OBLITERATIVE VASCULAR DISEASE BY INTERMITTENT VENOUS OCCLUSION FURTHER OBSERVATIONS

BY

J. J. MASON BROWN, M.B., F.R.C.S.Ed.*Assistant Surgeon, Royal Hospital for Sick Children,
Edinburgh*

AND

W. MELVILLE ARNOTT, B.Sc., M.D., F.R.C.P.Ed.*Lecturer in Therapeutics, University of Edinburgh**(From the Laboratories of Clinical Medicine and Clinical
Surgery, Royal Infirmary, Edinburgh)*

We have already made a preliminary report on the use of intermittent venous occlusion in the treatment of obstructive vascular disease of the limbs (1937). The method was originally introduced by Collens and Wilensky (1936a), and was based on the observation of Lewis and Grant (1925) that following venous obstruction there is a reactive hyperaemia in the tissues distal to the obstruction, lasting for a period varying from one-half to three-quarters of the period of occlusion. As already described, the apparatus consists of an electric pump which raises the pressure in a cuff surrounding the affected limb. The cycle is controlled from the electric motor in such a way that the pressure is maintained for two minutes at two-minute intervals. The pressure in the cuff is regulated by a safety-valve, and can be varied from 20 to 120 mm. Hg. We have had the opportunity of applying this method of treatment to a variety of cases, but it is our intention to limit the discussion to the results obtained in cases of obliterative vascular disease only.

Defective peripheral circulation can be regarded as being due to (a) obstruction of the lumen of the vessel by organic disease—thrombo-angiitis obliterans or arteriosclerosis obliterans; (b) excess of vasoconstrictor tonus, a defect which operates principally on the smaller arteries and arterioles; and (c) a combination of the two preceding factors. A clear definition of the relative importance of these factors is necessary in all cases because they call for distinctive forms of treatment. The clinical investigation of these cases should include:

Points in Clinical Investigation

1. *A Full History.*—Particular attention should be paid to a history of intermittent claudication, nocturnal pain or coldness, pallor on exertion or elevation of the limb, and trophic changes. The degree of sweating, the rate of growth of the nails, and the consumption of tobacco should also be ascertained.

2. *Careful Palpation of the Limbs Exposed to the Same Conditions.*—By this means any significant difference in temperature between the two sides can always be detected. The presence of normal pulsation in the peripheral vessels excludes obstructive disease of the main arteries, whereas the absence of such pulsation is not diagnostic of obstructive disease owing to the relative frequency of anatomical anomalies in the course of the smaller arteries. An approximate estimate of the severity of the obstruction to the circulation can be obtained by the venous filling test of Collens and Wilensky (1936b). This test consists in

the observation of the rate of filling of the veins of the dorsum of the foot when the limb is transferred abruptly from the elevated to the dependent position. The normal time required for filling is eight to ten seconds. A more accurate index is provided by the reactive hyperaemia test described by Pickering (1933). The limb is placed in water at 35° C. for ten minutes and is then elevated until blanching occurs. A cuff surrounding the proximal part of the limb is now inflated to a pressure greater than the systolic pressure. The limb is replaced in the hot water for a further four and a half minutes; it is then dried, put in a horizontal position, and the pressure released. A bright red hyperaemic flush courses rapidly down the limb, and should reach the toes in a few seconds if there is no vascular obstruction. This test is of value both in diagnosis and in the estimation of progress, but as it necessitates a prolonged period of circulatory arrest we have hesitated to use it in cases with severe vascular obstruction.

3. *Oscillometry.*—The oscillometer gives a valuable indication of the degree of pulsation at all levels, particularly those in which the vessel is not accessible to palpation. In this way the site of the obstruction can be approximately gauged. The instrument consists of an airtight box containing an aneroid capsule so arranged that the pressure in the blood-pressure cuff connected with the instrument is equal to that on both sides of the capsule. The cuff is applied to the limb, and readings are taken at intervals of 10 mm. from 240 to 0 mm. To take a reading one side of the aneroid capsule is cut off from communication with the blood-pressure cuff by closing a valve, and the extent of the pulsations is measured by the excursions of the needle connected to the aneroid. The instrument is not accurate enough to enable significance to be attached to small variations, and although of great value in the diagnosis of obliterative disease is of little use for estimating progress.

4. *Estimation of the Degree of Nervous Vasoconstriction.*—The patients are exposed for a period of an hour in a warm room the temperature of which is controlled thermostatically. The temperature of the digits is then recorded thermo-electrically, after which sympathetic inhibition is induced by the method of Landis and Gibbon (1933) and the temperature again recorded. The degree of sympathetic tone is shown by the difference between the two temperatures. Landis and Gibbon secure the release of vasoconstrictor tonus in the lower limbs by the immersion of the arms in water heated to 47° C., and we have found this method entirely satisfactory, although we occasionally employ spinal or regional anaesthesia.

Classification of Cases

On the basis of the foregoing tests we have classified our cases into three groups: (I) those showing a normal response to sympathetic inhibition and normal oscillometric readings; (II) those with a very deficient rise in temperature and defective oscillometric readings; and (III) those with only slight restriction of temperature rise but with a considerable deficiency in oscillometric readings. Group I comprises the cases associated with vasospasm and without obstruction; these have been excluded from our present series. Group II includes the cases of obliterative arterial disease with considerable deficiency in the collateral circulation. Group III comprises those cases of obliterative arterial disease with a good collateral circulation that are often attributed to a combination of vasospasm with obstruction.

apparent than actual. The fault or the deliberate tactics of counsel may prevent the truth from emerging. For example, it is the truth that food poisoning produces gastro-enteritis, but this must be modified by the undoubted fact that gastro-enteritis results from many different causes besides food poisoning. If medical evidence were given in the form of answers to an intelligent questionnaire there would appear more agreement than disagreement amongst medical experts. But counsel may not desire to achieve such agreement, and the zeal for victory rather than for the elucidation of truth may bring even medical witnesses into unwitting partisanship.

How Foods can Affect Health Adversely

A food may be deleterious either because of its own quality or of the constitution of its consumer. Even unaccustomed foods, good in themselves, or undesirable mixtures of harmless ingredients, may yield the same results as food defective in quality. Unwise drinking or extreme variations of temperature may produce a dyspeptic state without any fault in the food. Certain foods may affect in a specific manner individuals susceptible to them, gastro-enteritis may arise, with urticaria, alarming to the sufferer, but again not poisoning. Idiosyncrasy may manifest itself at any period—a point difficult to make clear to the person whose mind is filled with the suspicion that he has been poisoned by food. Obviously illness due to idiosyncrasy, although technically a form of food poisoning, cannot be laid at the door of the purveyor of the food. Nor is he responsible for the consumer's digestive weakness or his reckless dietary admixtures.

Food poisoning proper is the result of the presence of some noxious agent in the food. In the form in which it comes most frequently to medical attention it is due to the presence of specific germs or toxins originating, if in meat, in the animal from which the meat was taken or from some carrier handling the meat, or from sewage, as in oysters contaminated with typhoid germs, or in milk handled by a carrier of scarlet fever or typhoid, or, as has been learned recently, in pastries and piecrusts infected by a common staphylococcus. Again, there may be contamination of potted meats by a bacillus rare in this country—namely, the *botulinus*—leading to poisoning of a characteristic nature, with acute and rapidly fatal symptoms of paralysis of the nervous system. The medical jurist, however, is concerned with a much wider group than this, and his function is to prove whether a train of symptoms is the result of food unfit for human consumption.

The first inclination is to view the last meal with suspicion; but the last meal may have had nothing to do with the symptoms. Certain foods, such as shellfish, mushrooms, and ice-cream, are often suspect, and the sufferer is apt to go back several meals to locate such an article of diet, but here again the suspicion may be quite unfounded. Surmise is not proof, and it is not right to work on such generalizations as that oysters cause skin diseases or sausages gastro-enteritis. Many other possible causes enter into the story.

Proof of Food Poisoning

The various groups of poisons act in fairly constant ways. Each of the alkaloids produces its own train of symptoms by its selective action on the body, generally the nervous system; for example, strychnine produces spasms and twitches, nicotine acts on the nerve-endings of the heart, morphine acts on the higher centres in the brain. The toxins of poisonous fungi which are eaten in mistake for mushrooms act directly and with great severity on the nervous system as well as on the gastrointestinal tract, and symptoms of giddiness, stupor, convulsions, and coma are pronounced. I can find no evidence that severe and long-persisting skin diseases have been produced by mushrooms, though that has been the basis of many claims. In one unsuccessful action concerning alleged mushroom poisoning it was stated that the diarrhoea and vomiting had accompanied an erythema multiforme which persisted, but this picture is totally

different from the recognized results of poisoning by toxic fungi. Food poisoning as generally understood is characterized by gastro-enteritis, with pain, vomiting, and diarrhoea. It is an acute illness, ending rapidly, generally without fatal result, and leaving no after-effects.

The causes of gastro-enteritis are numerous, and therefore it is essential that proof of the food eaten and its causal connexion with the symptoms should be obtained in the early stages. The previous condition of the patient, the onset of the illness, and the time elapsing since the suspected food was taken are all-important. These circumstances should indicate whether there is a suspicion of a bacterial infection. Bacterial food poisoning has an incubation period during which the bacteria form toxins, and therefore several hours elapse before symptoms are manifested, though if the toxins are already present in the food before it is eaten the symptoms appear more rapidly.

It is important to know whether severe diarrhoea and vomiting occurred, also the nature of the flux. On two occasions I have been called to a case of alleged food poisoning following an unusual meal. Fortunately there remained some of the vomitus and diarrhoeic flux, which were typical of haemorrhage from a peptic ulcer, but it was difficult, in the absence of previous symptoms of ulcer, to persuade the patients of the seriousness of the illness and to get them to absolve the food. In another case of vomiting and later intractable diarrhoea the practitioner, without seeing the excreta, diagnosed food poisoning, but it came out in consultation that the claimant had been treated for many months at hospital for ulcerative colitis, which is not associated with food poisoning.

Cases occurring in Groups

A number of cases occurring together in similar circumstances is, of course, highly suggestive of food poisoning. But here again it is well not to jump to conclusions.

In one instance cream was alleged to be the cause of scarlet fever. Two ladies who had partaken of the cream were affected, and their two men companions, who did not partake, did not suffer. But it was found that the same cream was liberally used in sauces of which they all partook. Further inquiry showed that one of the ladies had just left a scarlet fever case, and it was suggested that she transmitted the infection to the other in her greeting kiss, while the men were not so exposed.

Unusual conditions must also be borne in mind in dealing with outbreaks. Recently in London there have been several scattered outbreaks of diarrhoea and vomiting due to the *Sonne* bacillus of dysentery. Epidemics of sickness and vomiting have also occurred, described under the name of *nausea epidemica*, which cannot be traced to food poisoning. Sometimes agonizing pain is an outstanding symptom, accompanied by vomiting and perhaps some diarrhoea, and as it follows a meal away from home the food is incriminated. But a careful history and examination will point to gall-bladder trouble or some other colic, which may indeed have been aroused by an unusual meal, but here again the purveyor of the food is not blameworthy.

On what grounds, then, can an uncontrovertible diagnosis of food poisoning be made? The symptoms can only point to food as suspect, the suspicion becoming stronger if more than one case occurs and a common origin can be suggested. Proof absolute would be demonstration of the toxic virus itself, and here we have a recognized procedure, often, but not always, successful. This includes the finding of the germs in the excreta and if possible in the remainder of the food, and administration experimentally to laboratory animals. It often happens, however, that the remaining food, or even the excreta, is not obtainable; then a test may show that the infected individual forms in his blood, after such infection, demonstrable antibodies. In a recent case in which pork chops were alleged to be the cause of the disease, it was on the demonstration of the agglutinins to Gaertner's

be nullified by persistence in the use of tobacco. We therefore insist that our patients should stop smoking.

Summary

1. A further series of cases treated by intermittent venous occlusion has yielded encouraging results.

2. The treatment is especially suitable in cases of obliterative arterial disease with a poor collateral circulation.

We are again indebted to Professors D. M. Dunlop and Sir John Fraser for their interest and help, and to the physicians and surgeons of the Edinburgh Royal Infirmary, who have kindly permitted us to treat their patients. The work was carried out during the tenure of a Syme Surgical Fellowship (J. J. M. B.) and the Shaw Macfie Lang Fellowship (W. M. A.). We also gratefully acknowledge a grant from the Earl of Moray Endowment towards expenses.

FOOD POISONING*

BY

JULIUS BURNFORD, M.B., D.P.H., F.R.C.P.

Senior Physician, West London Hospital

To the clinician food poisoning has a definite significance. It refers to a state of ill-health resulting from food which contains some abnormal or noxious content. Although the condition may be brought about by various agents, these are definable and produce manifestations which, within the limits of clinical medicine, are fairly constant for the agent concerned. To the lawyer, on the other hand, the term "food poisoning" has no significance; it is not even a legal expression, though were it not for the legal aspect the whole problem would be less complicated.

Responsibility of the Food Purveyor

The Food and Drugs Administration Act makes it an offence to sell to the prejudice of the purchaser any article of food which is not of the nature, substance, or quality of the article demanded. There are provisions in public health legislation directed against the offering for sale of meat, fish, milk, and other foods which are diseased, unsound, unwholesome, or otherwise unfit for food. Gross conditions such as these come within the purview of the sanitary authorities, which have special machinery for dealing with them, rather than within that of the practitioner. Even if the food be eaten it does not follow that poisoning would result.

The purchase of food implies a warranty that it is fit for consumption. Actions for damages for food poisoning (to use that common but often misused expression) are based either on negligence or on breach of an implied warranty of fitness. The provision in the Sale of Goods Act, 1893, material for this purpose is as follows:

"Sect 14. (1) Where the buyer, expressly or by implication, makes known to the seller the particular purpose for which the foods are required, so as to show that the buyer relies on the seller's skill and judgment, and the goods are of a description which it is in the course of the seller's business to supply . . . there is an implied condition that the goods are reasonably fit for such purpose. . . ."

Whether the case is based on the implied condition that the food is fit for consumption or on the breach of the seller's

duty to his customer to exercise care, damages are recoverable. In so far as the ground is negligence it is now clear that the legal responsibility goes back beyond the immediate supplier of the article of food to its ultimate manufacturer. This was decided in 1932 by the House of Lords in the case of *Donoghue v. Stevenson*, overruling the Court of Sessions in Scotland.

A shop assistant had purchased at a café in Paisley a bottle of ginger beer. The bottle was of opaque glass. She drank some of the contents, and when the remainder was poured into the tumbler a decomposed snail made its appearance. The woman claimed damages from the manufacturer, averring that the nauseating sight, coupled with the impurity of the liquid she had consumed, had caused her shock and gastro-enteritis. The House of Lords decided by three opinions against two that the manufacturer of food, medicine, or the like, sold by him to a distributor in circumstances which prevented the distributor or the ultimate consumer from discovering any defect in it by inspection, is under a legal duty to that consumer to take reasonable care that the article is free from defect likely to cause injury to health.

When the claim is based on the implied warranty it is immaterial that the purveyor of the food could not himself have discovered the defect. He has warranted to supply safe food, and this warranty is absolute. This is established by the case of *Frost v. Aylesbury Dairy Company*, which came to the Court of Appeal in 1905, in which milk was held to contain typhoid germs. The existence of such germs could only have been discovered by prolonged investigation, so that the defect was not discoverable at the time of sale, but the plaintiff's right to damages under the implied condition of fitness was upheld. The question of negligence, therefore, need not arise, and I presume that is why the usual course is to found the claim on implied warranty.

The Wide Field of Possible Complaint

Man must eat to live, and man is one of the few animals with widely variable tastes. Hence arise innumerable possibilities for complainants. There are various illnesses of cryptic origin which puzzle medical men and in which the tendency of the sufferer is to ascribe the blame to a meal just taken, all the more so if the meal included some article of diet, such as mushrooms, lobster, or ice-cream, which the public mind associates with disease. Again, one man's food is another man's poison, and individual idiosyncrasy adds to the difficulty of proof of damage or disproof of causal connexion.

The crux of the question when a person alleges that he has been affected adversely by consuming deleterious food is whether he has actually suffered from such food, and if so whether the defect in the food was due to negligence in its manufacture or supply. Both these are questions of fact, the first essentially, and the second largely, material for the medical witness. The fraudulent claim is common, and often based on the supposition that the big firms are rich and will pay to avoid publicity. At the same time, there is also the individual who honestly believes that he has been made ill by some special article of food. He is perhaps influenced by a chance observation by his medical attendant that he might have taken some food which had upset him. He instantly translates "food upset" into "food poisoning." Sometimes the medical man himself is a credulous person, and accepts the patient's statement of his subjective symptoms—as, for example, diarrhoea and vomiting—without verifying it. Yet the essence of proof of poisoning rests on a detailed investigation in the early stages of the illness.

A legal action once started may drag on for a long time before the case is actually heard, and as time goes on the patient's symptoms, as imagined by him afterwards, tend to multiply. Generally, however, this is to the advantage of the defendant, for the symptoms become so numerous and complicating as to contradict one another. To add to the difficulty, a difference of opinion may arise among the experts called in—a difference apt to lead to the discredit of expert evidence. I suggest that the difference is more

* The substance of a paper read before the Medico-Legal Society on November 25, 1937

I regard food poisoning as an acute illness from which the patient makes a rapid recovery, and I cannot believe that chronic states of skin disease and intestinal trouble can follow even an actual case of food poisoning, let alone an imaginary one.

The problems are numerous, and I have touched only on some of them. Each case must be dealt with on its merits. It is obvious that the medical expert called in to weigh evidence must approach the subject in a different manner from the clinician. On the medical expert falls the onus of discovering proof. His outlook must be wider, and he must be careful lest he, too, like possibly the patient or claimant, become the victim of credulity. In view of possible sequels in court he should be prepared to produce all the proofs of his investigations and all the clinical deductions, bearing in mind that in this field especially the time factor is of importance because of the rapidity with which the evidence may disappear.

Clinical Memoranda

Weil's Disease following a Motor-car Accident

Although cases of Weil's disease have been reported in increasing numbers in recent years, it has been suggested (Maxwell, 1935) that all sporadic cases be put on record. I am therefore contributing the following case.

CASE RECORD

X. Y., a man of 55, was driving a saloon motor-car containing two other people and a dog. He failed to take a turning over a canal bridge properly, and crashed into the canal—the Fossdyke Navigation Canal, which is the oldest canal in Britain, being a relic of the Roman occupation. The car came to rest upside down, with only the wheels visible above the water. Bystanders on the canal bank dived immediately to the rescue. The two passengers—an old lady and her husband, who was partially paralysed—were rescued first, and then the driver, who was therefore immersed for few minutes, as the doors of the car had to be forced open under water. Artificial respiration was applied to all three on the canal bank, and it was some time before they were taken round. As soon as they could be moved they were carried by ambulance into Lincoln County Hospital—a distance of about six miles. The two older people were recovered as stretchers, but X. Y. had by that time so far recovered as to walk in. They were all treated for shock and partial drowning. The male passenger made an uneventful recovery. His wife also fully recovered, but for some time was very ill with bronchopneumonia. The driver of the car, whose case is here recorded, improved gradually. He stated that he had swallowed a good deal of the canal water, and often asserted during his illness he came kept on tasting it. Five days after admission he complained of severe cramp-like pain in his legs. On being questioned he gave a history of phlebitis, and said that he had had similar pains before. Except for these pains he continued to be quite well, and was considered fit enough for discharge ten days after admission. On that day he complained of sickness and malaise, and his temperature for the first time was above normal. The next day he was very vomit, and jaundice was noticed. The next day he was jaundiced, and complained of pain in his chest and epistaxis occurred the following day; the jaundice meanwhile continued to deepen. A clinical diagnosis of Weil's disease was made. He died twenty days after admission, fifteen days after first complaining of jaundice. The urine contained bile, albumin, pus cells, epithelial cells, and coliform bacilli. The van den Bergh reaction was biphasic.

At necropsy the liver was found enlarged and friable. The left kidney was very soft and friable, and there were haemorrhages into the suprarenals. On naked-eye examination nothing abnormal was found in the stomach, intestines, heart, or spleen. The lungs showed a few old healed tuberculous lesions at the apices and some terminal hypostatic congestion. Microscopical examination of sections from liver, kidney, and spleen showed *Leptospira icterohaemorrhagiae*. The organism was not seen in sections from the lungs.

Discussion

The above was a typical case of Weil's disease with a fulminating course. The incubation period was five days if the first complaint of pain is taken as denoting the onset, and ten days if the sickness and malaise are considered the first symptoms. Schüffner (1934) found that in cases where the patient fell into infected waters the incubation period varied between four and nineteen days. A case following bathing has been reported (Lendrum, 1936) in which the incubation period was only two days.

Bathing in, or falling into, infected waters is a fairly common mode of infection. Alston and Brown (1937), in a series of 142 cases, found that it was the fourth largest group. Bewley and Wilson (1937) note that the disease occurs in a greater proportion of those who fall into infected waters than of those who bathe in them. This is borne out by the above case, as the canal is used for bathing by very many people during the summer. Schüffner points out that this greater incidence is due to the fact that an unpremeditated immersion often causes violent struggling, so that water enters the respiratory tract. Infection usually occurs through broken skin or through the mucosa of the nose, mouth, or upper respiratory tract. No organisms in the above case were found in sections from the liver; and infection seems to have been from the swallowed water. It is unusual for infection to occur through the acid in the stomach and the bile antiseptic action of the organisms. Carnot and Weil (1934), however, report the case of a woman who, attempting suicide in the Seine at Paris, swallowed a large quantity of contaminated water. She developed spirochaetal jaundice; profound anorexia ensued, and death took place from inanition.

In the clinical course the above case followed the classical description, except that it was a fulminating one. The fatality rate in Weil's disease varies from 5 per cent. to 50 per cent. (Alston and Brown, 1937). The disease may be very mild and jaundice is not always present, diagnosis depending on serological reactions. Many cases may therefore be missed, being of subclinical types. This accounts for the differences in mortality rates.

Summary

A case of Weil's disease is described, and the incubation period, mode of infection, and mortality rates are discussed.

I have to thank Mr. G. C. Wells-Cole, senior surgeon, Lincoln County Hospital, for permission to publish this case.

bacilli in the blood that the action was decided. There are certain reservations to be made in drawing conclusions from such tests. Previous infections may leave agglutinins in the blood for a varying period, but the discussion of this matter is for the expert. I would stress only the importance of duplication of tests to avoid errors in technique, and the tests should be carried out in laboratories specially equipped for the purpose, or, better still, in a central laboratory, where the stock strains are of recognized accuracy. It must also be remembered that laboratory tests may fail at times owing to long delay in beginning the investigation. That errors can arise owing to the refinements entailed in identification of the bacteria and their products was impressed upon me whilst investigating an outbreak of sore throats following a banquet.

Some sixty of the diners went down with sore throats, in some cases followed by scarlet fever. At first a streptococcus isolated from the throat of the chef was thought to be the causal organism, but later reports from the Ministry of Health laboratories showed that the streptococcus so obtained was not the one associated with the conditions in question. Cream or ice-cream was suggested as the cause of this outbreak, but no bacteriological corroboration was forthcoming. It is obvious that when gatherings take place in a crowded banqueting hall the atmosphere may be such as to encourage the spread of any infection, and I could find no reason to blame the food despite the coincidence of so many cases.

Popular Fallacies about Food Poisoning

It is desirable to rebut certain popular fallacies. Bacteria are not necessarily noxious, nor is decomposing food necessarily poisonous. Many foods are eaten, from choice, in a high state of decomposition. It is a fallacy that poisoned food has a bad taste; it is the decomposing food which tastes, and indeed the decomposition is a safeguard, preventing stale food from being eaten, for in stale food dangerous germs may have had time to form their toxins before cooking takes place.

Ordinarily, food poisoning is an acute illness in which the patient gets rid of the poison by vomiting and diarrhoea and is better within a few days, suffering no after-effects. Cases due to toxins which attack the nervous system take a more fatal course, as, for example, in the fatal outbreak of botulism in 1922 at Lochmarea, when all the eight persons who had eaten sandwiches made of potted wild duck paste died.

The source of the infection is important in making investigations. It may come from the animal itself (and if the animal be diseased the whole carcass will be infected, so that there will be widespread incidence of food poisoning); from butchers and others who handle meat actually infected or are themselves carriers of disease germs; or from the fouling by vermin such as rats and mice of cooked food improperly stored.

The bacilli are destroyed by heat and cooking, but the toxins remain unaffected and potent for danger. Hence delay in the canning process after slaughter will allow of toxins being developed and conveyed in the sterilized food. A debatable point has been raised in court as to whether the temperature of cooking is sufficient to destroy bacteria in the depths of meat. Some experiments which were carried out for me appeared to demonstrate that possibility. Minor questions arise such as whether a portion of tinned meat can be infected and not the rest of the meat in the tin. This has been taken to explain an isolated case and the immunity of others who shared from the same container, but I regard it as unlikely in view of the process of canning.

"Psychological" Food Poisoning

Many claims are based upon the discovery of a foreign body in the food, as, for example, a piece of glass or a nail, a slug in a salad, or, as in the case already mentioned, a decomposed snail in a bottle of mineral water. Cases of this kind need looking into very closely. It

is not unknown for a cockroach to be produced from a match-box and placed in the soup by the prospective claimant. One case is on record in which a rat's tail had been introduced into a meat pie. This proved unfortunate for the claimant, however, for it was shown in the laboratory that the tail had not been cooked in the cooking of the pie. In one case which I investigated the claimant had been twice successful in contending that he had inadvertently swallowed pins found in food, and it turned out that the failure to expose his fraud was due to a too trusting radiologist. The radiologist, believing the man's story, and seeing the pins in various positions in successive radiographs, which had been taken only in one plane, was completely deceived. Apparently the man knew enough to place the pins on his back in appropriate positions to suit the time intervals. The swallowing of foreign bodies may, of course, be attended by harm, but in most cases the glass or pins are passed through the bowel without damage, and so the matter should end; but it may not so end if a large firm or insurance company is concerned and can be regarded as "fair game" by some claimants.

If a woman finds a slug in a salad and discards it without having tasted any of the food, does that constitute a just claim for damages? It is an unpleasant occurrence, but not enough to cause illness. Had she found the slug while preparing a salad in her own kitchen, would she not have removed it and served the salad? But apparently it is a more expensive slug which makes its appearance at restaurants!

In one case with which I had to do a woman tasted three mouthfuls of a chop, which she said was "tainted," but she followed it with fruit salad and cream, and then came the usual story of vomiting and diarrhoea, pains, and in this case an urticarial eruption with nausea. Her practitioner argued that, although this was not specific food poisoning, the tasting of tainted food by a highly sensitive woman caused an upset of digestive functions of a psychological nature.

Is this possible? And, if such sensitive persons exist, can the food purveyor be justly held responsible for their susceptibilities? Carried to a logical conclusion, such people would be equally upset by the presence of a deformed person or a person of unpleasant countenance in the restaurant. I am inclined to think that if such susceptibility exists it is in no way different from susceptibility regarding certain foods, and should be the entire responsibility of the individual unfortunate enough to possess it.

Medical experts differ regarding these quaint cases of what may be called psychological food poisoning, but to me it seems unfair that damages should be given in such circumstances. I hesitate to dwell upon the medical and legal possibilities if at a modern restaurant crowded with sensitive, fragile, twentieth century females the old nursery rhyme were re-enacted:

"Four and twenty blackbirds, baked in a pie.
When the pie was opened, the birds began to sing."

But perhaps the writer of a "Song of Sixpence" properly assessed the amount of the damages!

After-effects of Food Poisoning

A final word must be said on the after-effects of food poisoning. I have referred to a case of ulcerative colitis alleged to have followed poisoning by food, and I have notes of a case in which an attack of appendicitis was said to have followed the eating of tinned salmon. In this case it was obvious that the whole of the symptoms ascribed to the tinned salmon were actually due to the appendicitis. In the case mentioned above in which a woman had merely tasted a tainted chop, it was said that recurrent attacks of urticaria supervened, and for this she demanded compensation, with the proviso that she be allowed to reopen the case at any time within the next ten years.

Malignancy and Evolution (1926) and *The Serpent's Fang* (1930). He bears willing testimony to the influence of that philosophic pathologist, the late Dr. H. G. Sutton of the London Hospital, on all his thought, but avows himself an impenitent neo-Lamarckian.

This retrospect is not irrelevant, for *Bio-politics* is an attempt to codify the ideas expressed in his earlier books and to extend them to the whole body politic. He visualizes a human community, however, not so much as following the pattern of a complex metazoan type as that of the colonial protozoa. Curiously enough the idea of an evolution of colonial protozoa to the stage of a group-mind was elaborated also in Olaf Stapledon's novel *Last and First Men*, where our earth was invaded by Martians moulded on that pattern.

We hope it will not appear discourteous to a veteran controversialist if we call attention to a few points which seem to us to militate somewhat against the usefulness of his book. If he is out to convince, we would remind him of the old fable of the contest between the sun and the wind to compel the traveller to divest himself of his cloak. In a book professing rigid scientific argument, is not so much sarcasm and scorn out of place? The politician may be invincibly ignorant, but why bludgeon him? Mr. Harold Nicolson has not taken it lying down, but in a spirited rejoinder has given as good as the politician got. Among other things he calls attention to Mr. Roberts's admission that there must be castes in human society corresponding to the higher and lower functions of an organism. Wherein then lies the validity of the analogy with low-grade organisms such as colonial protozoa? No high degree of development or co-ordination is possible without a central nervous system. As an outcome of this wordy encounter we are reminded of Lord Baldwin's dictum that the function of the politician is to tell the expert just what the people will not stand for.

Again, the copious use of analogy has its dangers. Comparative anatomists rightly insist on the difference between analogy and homology. Analogy often provides an illuminating parable, but homology implies a basic organic similarity. We are not sure that all Mr. Roberts's analogies rest upon this firm foundation. Yet again, his conception of hostile symbiosis between every cell leads him to most pessimistic conclusions as to the possibility of peace ever being more than a temporary lull between wars. The face of Europe to-day might well be taken to support this contention. But consider the state of England during the six centuries between the end of the Roman occupation and the Norman Conquest; invasion after invasion by races of different blood and the establishment of a heptarchy. The Devil's Dyke near Cambridge, erected to keep out the Mercians, still stands. But no longer does Mercia desire to invade East Anglia, nor is a Wessex-Mercian axis practical politics. The symbiosis is more evident than the hostility, which has perhaps been "sublimated" into cup-tie contests. Mr. Roberts may retort that pressure from the external environment may promote unity within. Perhaps so, in which case threats from the East may yet produce a Europe so united in defence of its civilization as to be beyond attack.

But we would not withhold our meed of admiration for Mr. Morley Roberts's dogged determination, in the face of ill-health and other obstacles, to place the coping stone by this book on the philosophic system he has constructed. It is a remarkable effort, worthy of much praise, and we can fairly assert that orthodox biological and medical thought owes more to him than is often recognized.

SURGERY

The Science and Practice of Surgery. By W. H. C. Romanis, M.B., M.Ch., F.R.C.S., and Philip H. Mitchiner, M.D., M.S., F.R.C.S. Vol. i, General Surgery; vol. ii, Regional Surgery. Sixth edition. (Pp. 883 and 1053; 800 illustrations. 14s. each volume.) London: J. and A. Churchill Ltd. 1937.

A sixth edition of *The Science and Practice of Surgery*, by Romanis and Mitchiner, testifies to its continued popularity during the ten years which have elapsed since its first appearance. This is deserved, for it remains one of the best textbooks for the student, concisely and clearly written, well illustrated, and descriptive of current surgical practice. The latest edition contains a new section on the medical aspects of exposure to poison gas, and the chapters on fractures and dislocations have been largely rewritten so as to bring them into line with more modern views of treatment. Other sections of the book in which there has been extensive revision are those on anaesthesia and the sympathetic system. In the preface to this edition the authors remind us that the book is intended primarily for students who are required to meet the syllabuses of examining bodies, and that several methods of diagnosis and treatment are therefore discussed in dealing with each pathological condition rather than an arbitrary laying down of personal practice in these cases. Quackenstedt, pages 8 and 137, vol. ii, should be Quackenstedt.

Like good wine, this work apparently improves with age. This is the best edition that we have seen, and should be much in demand by the students for whom it is written.

DRUG BOOK FOR QUICK REFERENCE

Index Médico-Pharmaceutique. Edited by N. T. Delsanu, René Fabre, and L. Coniver. Preface by M. Maxime Radais. (Pp. 756. 488 pages of which are tables. 120 fr.: 150 fr. bound.) Paris: Masson et Cie. 1937.

This medico-pharmaceutical index, edited by Professors Delsanu and Fabre of the Faculty of Pharmacy of Paris and M. Coniver of the University of Bucharest, is based on the *Codex Médico-Pharmaceutic*, which was prepared and published in Rumania in 1927. It is intended to serve as an extra-pharmacopoeia which will give French-speaking doctors a book of rapid reference for problems relating to the composition, chemistry, and action of drugs. Articles on special subjects have been contributed by a number of different authors. For example, Professor Tiffeneau writes on the general principles of drug action and on chemotherapy. Other articles deal with poisoning, hormones, vitamins, prophylaxis of infectious diseases, etc. About two-thirds of the volume is occupied by an alphabetical index of drugs. This gives in tabular form their chemical, physical, and therapeutic properties, dosage, toxic actions, antidotes, and incompatibilities. The index contains about 1,200 titles, and in addition to the official drugs (that is, those contained in the French Pharmacopoeia) a large number of proprietary drugs are described.

From what is said above it will be seen that the arrangement of the volume differs in many ways from comparable British publications such as the *Pharmaceutical Codex* or the *Extra Pharmacopoeia*. In these latter all information relative to a drug is gathered under a single title, while in the book under review only a brief tabular account is given of the therapeutic properties of drugs, and about one-third of the text is devoted to general reviews of special subjects. The volume will be found particularly useful by practitioners in this country who wish to look up the chemical and pharmaceutical properties of drugs used in France.

Reviews

PRACTICAL RADIOTHERAPY

Radiation Therapy. Its Use in the Treatment of Benign and Malignant Conditions. By Ira I. Kaplan, B.Sc., M.D. (Pp. 558; 198 figures, 1 table. 30s. net.) London, New York, Toronto: Oxford University Press. 1937.

The need for a comprehensive and practical book on the therapeutic uses of x rays and radium has long been felt, and so it was with very considerable interest that we received a copy of Dr. Ira Kaplan's new book on *Radiation Therapy*. The author is well qualified for the important task he has undertaken, for, in addition to being director of some of the most important radiotherapeutic clinics in New York, he is also editor of the therapeutic section of the *Year Book of Radiology*. In all these capacities Dr. Kaplan has drawn upon his own experience in writing this useful and valuable textbook, and indeed always seems at his happiest when discussing some practical point arising out of his own clinical work. The indications where preference should be given to the use of either x rays or radium are clearly set forth, and we think he has done wisely in forgoing the lengthy preliminary sections which are often introduced into books dealing with the uses of x rays or radium. In general such accounts are calculated to give a wholly inadequate impression of the importance of experimental radiology as an essential study for all who intend to practise this important and difficult branch of treatment. We are so accustomed to think of radiotherapy as specially concerned with malignant disease that its extensive field of application in non-malignant conditions is apt to be overlooked. In the present work these important uses of radiation are clearly and concisely set forth, and wherever possible the theoretical considerations upon which the treatment is based are explained. Many will perhaps be surprised to learn that x rays have been successfully employed for the cure of such lesions as erysipelas and carbuncle. The curative effects are due not to the direct action of the rays on the micro-organisms concerned but probably to their disintegrating action on the leucocytes, whereby bactericidal substances are freely liberated. Many cases of asthma which respond unsatisfactorily to other methods of treatment have similarly been treated with success; and the same holds good of persistent cough in children where the aetiology is obscure. In dermatology many conditions receive benefit from x-ray therapy, and the author's experience with intractable and extensive psoriasis will certainly be of interest to all who are faced with its treatment.

"For persistent and resistant lesions we have found treatment over the sympathetic nervous system to be effective in controlling the condition. For this purpose the spinal area is divided into four sections, the cervical, upper and lower dorsal, and lumbo-sacral. The section treated corresponds to the region of the body involved with the disease—that is, if the chest is involved treatment is given to the cervical and upper dorsal spine; when other regions are involved the corresponding spinal section is treated."

Such are a few non-cancerous conditions, chosen on account of their general practical interest; but the list of such diseases in which radiation is successfully used is a long and ever-increasing one. The treatment of malignant disease is, of course, also discussed, but as it has been so often referred to in this *Journal* any more observations on the subject are here unnecessary. There are

two further points which call for mention. On page 23 the remarks on the examination of patients by the radio-therapist are calculated to give a wrong impression of his professional duties. Dr. Kaplan writes: "While as a rule the patient referred for irradiation has previously been examined and diagnosed, it is nevertheless advisable for the therapist to make an examination himself," and then proceeds to explain the various reasons for which such an examination is required. This might, with limitations, be appropriate to a technical assistant, but is hardly so to a member of the medical profession. The other point is concerned with irradiation of the ovaries and subsequent child-bearing. In spite of the author's fifty cases in which "normal" living children were born, we cannot help feeling that the subject is treated a little too lightly. The subsequent mental as well as physical development of such children and of their offspring will be a matter of great interest. At the same time the term "normal" must be interpreted with due reference to the social position of both parents and offspring.

There is every probability that a new edition of this very useful book will soon be called for; if so, it is to be hoped that every page will be carefully examined, as there are a number of typographical errors, which we are unaccustomed to see in works issued by the Oxford University Press. The present volume is printed and published by the American branch of the firm, who in other respects seem to have done all that the most critical author or reader could desire.

BIOLOGY AND THE BODY POLITIC

Bio-politics. An Essay in the Physiology, Pathology, and Politics of the Social and Somatic Organism. By Morley Roberts. (Pp. 240. 15s. net.) London: J. M. Dent and Sons, Ltd. 1938.

Mr. Morley Roberts in his time has played many parts, and each of them with zest—in turn sailor before the mast, rancher, novelist, and biologist. His *Bio-politics*, published on his eightieth birthday, shows that his natural force is not abated. Starting from the axiom that the laws of biology apply to man and his institutions as strictly as to the amoeba, he proceeds to analyse all human activities from that standpoint and to deduce sociological conclusions, particularly for the benefit of the politician. It may be thought that there is nothing new in this method of approach. That remarkable man, Walter Bagehot, did it in his *Physics and Politics* when Darwin's *Origin of Species* was causing evolutionary ideas to permeate all fields of thought. More recently Mr. Wilfred Trotter's brilliant essay on *The Instincts of the Herd* attracted much attention in the same direction, and Sir Arthur Keith has posed the question "Does Man's body resemble a commonwealth?" with his accustomed lucidity. What however was new in Mr. Morley Roberts's *Warfare in the Human Body* (1920) was his insistence on the effect of pathological lesions on the process of evolution, and it was this which made his work of interest to medical men; stress, breakdown, and repair were claimed as stepping-stones to higher things. His sturdy materialism would, however, resent any such teleological gloss as that good thereby came out of evil. Indeed he might point to Sir Frederick Andrewes's fascinating lecture on "The Evolution of the Streptococci" as proof that by the same steps a harmless saprophyte became a dangerous enemy to man. Good for the streptococcus no doubt, but evil for its host! The other *leit-motif* is "hostile symbiosis" as a definition of the conditions obtaining between the different tissues by which a *modus vivendi* is established. Mr. Roberts elaborated the same theses in

MEDICAL RESEARCH COUNCIL

REPORT FOR 1936-7

If a reviewer ever trembles he might well be excused for doing so when confronted with the annual report of the Medical Research Council, the body which by its allocation of Government funds and funds from private sources ordains to a large extent the direction of medical research in this country.¹ The report comprises 196 pages, and it covers the range of medicine. Fortunately for the reviewer, however, this document is in the main an epitome of what has already appeared during the year in certain journals or special publications or has been discussed in medical societies, so that one is conscious of travelling over familiar territory. Over a hundred such contributions appeared during the year from workers at the Council's own central laboratories, the National Institute for Medical Research at Hampstead, and many others from external workers receiving in one form or another grants-in-aid; but set out in the succinct form of the present report the impression is given of an army of research pursuing its objective through many highly specialized units.

Many-sided Investigations

Over twenty investigation committees for special subjects have been set up by the Council, the subjects including clinical science, therapeutic trials of new remedies, anaesthetics, nutrition, dental diseases, mental disorders, tuberculosis, vision and hearing, hormones, bacteriology, cancer epidemics, chemotherapy, and statistics. The Industrial Health Research Board, which assists the Council, has set up half a dozen more, including committees for industrial pulmonary diseases and industrial psychology. The National Institute has a staff of over forty professional workers. The Council, by the way, has decided in principle—the scheme awaits a final decision on the ground of cost—to abandon the Hampstead site of the Institute and to concentrate the whole of the work at Mill Hill, where, fifteen years ago, it purchased a considerable property.

But the Council does not put all its golden eggs in the National Institute basket. It supports clinical research units at three London hospitals—University College, Guy's, and Queen Square. It also makes grants in aid of research work in different institutions throughout the country. Another development is one under which appointments are made to the Council's staff for work in external institutions. In this way every department of medicine is covered, and most notably clinical medicine. Arrangements have also been made by the Council, in consultation with the Colonial Office, for the promotion of a more extensive programme of research in the field of tropical medicine; this is now in its second year, and work is being done on a number of specified subjects, including trypanosomiasis, yaws, yellow fever, and pellagra. One pleasing circumstance is the resumption and augmentation of the Rockefeller fellowships. The award of these was suspended a couple of years ago, the Rockefeller Foundation deciding to concentrate on certain special fields of research activity, but this year once again seven Rockefeller Fellows have been appointed by the Council and are all at present working at centres in the United States. In the special field of tuberculosis the Council has itself

awarded a further series of four research fellowships, and the holders are at present studying problems of tuberculosis abroad.

Research in Chemotherapy

Chemotherapy, the administration of chemical compounds synthesized in the laboratory and found to have a specific action on the infected organisms causing particular diseases, is this year on the first page of the programme. Following the submission of proposals by the Council, the Government has approved an additional sum of £30,000 a year with a special view to the development of research in this subject. The decision has been made not entirely on medical grounds but on the grounds of industrial opportunity and of national and colonial requirements. The investigation so far has scarcely begun, the first allocations being devoted to building and equipment.

Up to now the principal successes of chemotherapy have been in infections with spirochaetes and protozoa rather than with bacteria, but there is good reason for regarding the value of chemotherapy as likely to be established in infections of a bacterial nature also. The recent achievements in the treatment of streptococcal and other infections by the substance known as "red protosil" and the colourless substance of simpler constitution usually called sulphanilamide are pointed to as an encouraging indication, and a new field in chemotherapy has been opened up which is being effectively and rapidly developed.

Apart from such new directions, the chief role of chemotherapy has been in tropical diseases, and therefore the subject has a special significance for the British Empire. But the discovery and production of chemical compounds of value in this respect have depended, and still depend, almost entirely on German science and industry. The most notable exception to this—namely, tryparsamide—is of American origin. Several fundamental discoveries in chemotherapy have been made in this country; it was here, for example, that the trypanocidal action of atoxyl was first demonstrated, and here also that the similar action of tartar emetic was discovered and its value in bilharziasis established. The original discoveries have been made here, but the intensive researches for compounds superior to the original substance have been carried on abroad, and therefore the production has passed into foreign monopolies. The matter is more serious than one merely of prestige, for in the event of war the British Empire might find itself deprived of essential drugs. Obviously this is a matter which calls for a national scheme supported by public funds. Large research facilities are necessary to secure substantial advances in chemotherapy. The proposals include the setting up of a central research laboratory with a staff able to give their whole time to some most laborious investigation, and also the assignment of certain parts of the work to different academic centres.

The scheme will follow the general line of action of a great commercial organization like some of those in Germany, but with the extremely important difference that it will not aim solely at financial success. A commercial undertaking, again, would be likely to neglect the large amount of information of scientific but not of immediately commercial value incidentally obtained.

Sulphanilamide and Allied Substances

The work at Queen Charlotte's Hospital on the treatment of puerperal sepsis with protosil is already familiar. It is touched upon again in the present report. The work has since branched out to other streptococcal infections

¹ Report of the Medical Research Council for the Year 1936-7. Cmd. 5671. H.M. Stationery Office. (3s.)

SKELETAL MATURATION

Atlas of Skeletal Maturation. By T. Wingate Todd, M.B., Ch.B., F.R.C.S. (Pp. 202; 4 tables, 75 plates. 31s. 6d. net.) London: Henry Kimpton. 1937.

Some standard yard-stick for the measurement of the normality or delay of physical growth is badly needed by those concerned in the care of children, and Professor T. Wingate Todd's *Atlas of Skeletal Maturation* will be welcomed for offering a possible solution to this problem. This volume appears to be one of a series, for after over thirty pages of introduction the reader is led to a section headed "Part I—Hand" with twenty pages of text and over eighty illustrated by x-ray pictures of the hands of children, male and female, at different ages from three months to over eighteen years, each with appropriate comments according to a special plan. Probably something like a million skiagrams have been examined by the author and a large team of associates, and this gigantic task has yielded an atlas of standards of first-rate scientific importance. Three preliminary surveys have been discarded, and the final selection here presented offers few grounds for criticism. For the accurate treatment of retarded children the first essential is a precise and reliable method of measuring the stage of maturity. This is now afforded by Professor Wingate Todd's work, upon which he and his collaborators are to be sincerely congratulated.

Notes on Books

Students attending the short course in bacteriology which forms part of the ordinary medical curriculum often prefer to use a textbook containing only essentials and simplifying the subject as far as it reasonably can be. Among such books Dr. L. E. H. WHITBY'S *Medical Bacteriology*, which has now appeared in its third edition (J. and A. Churchill, 11s. 6d.), has become a popular choice. Concise writing, together with a profusion of well-drawn if perhaps rather over-diagrammatic illustrations, makes it attractive and readable, and in some respects the information given is remarkably full for a work of such modest size. This edition contains a new chapter on theories of immunity, a rather surprising revival of an aspect of the subject which has lost favour in most elementary teaching of recent years. The chapters on protozoa and animal parasites are a valuable feature, and the extensive concluding section on applied bacteriology will doubtless be of value, more perhaps to the practitioner than to the student, but its advocacy of vaccine treatment for such conditions as arthritis, colitis, and "intestinal toxæmia" must be regarded as a departure from the strictly scientific outlook of the earlier pages.

Crossen's *Operative Gynaecology*, first published in America in 1915, has long been well known in this country. It is a book which has proved useful to many gynaecologists and to surgeons embarking upon pelvic work. A fifth edition, entirely revised and reset, has now been prepared by Professor H. S. CROSSEN and Dr. R. J. CROSSEN after an interval of seven years. New knowledge, physiological, anatomical, and therapeutic, has been thoroughly sifted by the authors, and in the course of rearrangement and rewriting they have held to the principle that underlay previous editions: "The selection of the operative measure most suitable for the particular modifying conditions present in that patient, instead of trying to apply one operation to all classes of lesion regardless of type and details." The illustrations, as before, are very numerous, and many new drawings have been included. This handsome volume of 1,076 pages is published by Henry Kimpton at 52s. 6d. net.

Nuevos Estudios sobre los Neumotórax Espontáneos consists of a series of beautifully illustrated papers on spontaneous pneumothorax by MARIANO R. CASTEX and EDIGIO S. MAZZEI. Most of the papers were originally read before the National Academy of Medicine in Buenos Aires. The first article deals with the anatomy, radiography, and pleuroscopy of subpleural bullae; the second with benign spontaneous pneumothorax caused by their rupture; and in the third is described the recurrent form of pneumothorax. In another article the relation of spontaneous pneumothorax to asthma and emphysema is discussed, and in yet another the uncommon painful forms of spontaneous pneumo- and haemothorax. In the last chapter the authors discuss fully the causation and treatment of spontaneous pneumothorax (and its complications) in the course of pulmonary tuberculosis. The bibliography at the end of each section of this book will be found a valuable feature. It is published at Buenos Aires by Aniceto Lopez.

The price of *The Silent Social Revolution*, by G. A. N. Lowndes (Oxford University Press), reviewed in the *Journal* of March 5 (p. 515), is 6s. net—20s.

Preparations and Appliances

RUBIAZOL

Rubiazol (Roussel Laboratories Ltd., 36, Cavendish Square, W.) is an interesting new derivative of sulphamido-chrysoidine (prontosil), which was discovered in 1936 by Girard. Its chemical name is carboxy-sulphamido-chrysoidine. Gley and Girard (1936) found that rubiazol was less toxic than prontosil and had a higher anti-streptococcal activity. Clinical trials in one of the largest maternity hospitals in Paris (3,598 cases) showed that the total number of days of hospitalization for cases of severe puerperal sepsis fell from 1,297 in 1934 to 162 in 1936.

The original prontosil was introduced in 1935, and the whole subject is too recent to permit judgment on the relative merits of the numerous compounds which have been introduced. Fortunately the difficulty in making such a decision is due to the fact that excellent results have been obtained with several rival compounds. The claims made for rubiazol are high, and it will be interesting to see whether it proves to have a clear superiority over sulphonamide.

LAMPS FOR ULTRA-VIOLET TREATMENT

A copy of the catalogue (No. 120) of Lumsden quartz lamps has been received. The outstanding introduction is the Lumsden "medical sun lamp," which is designed for general ultra-violet treatment by medical practitioners in private practice or in hospitals. The quartz mercury vapour lamp is of a new gas-filled discharge type, rich in its output of radiation, and requiring no tilting to start the arc. The reflector is made to move in all directions so that it can be rotated to a convenient angle and used either vertically or horizontally for sitting or recumbent patients. Doors are provided to focus or confine the light. The control unit containing the choke coil and resistances has a drawer to hold goggles and accessories. A word should be said about the attractive appearance of the unit. The body is finished in black and silver, and the reflector is matt silver outside and chromium-plated inside. Another device is the Lumsden "central sun lamp" for use in clinics where there are a large number of patients who are able to move about, doing exercises or even playing games during treatment. It consists of a central pillar with a triangular reflector around which are grouped three quartz burners so arranged that no matter where they stand patients up to twenty or more may be always under the rays of two burners but never of more. It is claimed for this equipment that it represents the most economical method attainable of irradiating a large number of patients with mercury vapour lamps.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MARCH 19 1938

MEDICAL RESEARCH IN BRITAIN

The Medical Research Council owed its origin to the "research penny" which, under a provision of the first National Insurance Act, Parliament undertook annually to provide. After five years' experience of its working the enlarged scope already granted to the Medical Research Committee (to give it its first name) was confirmed by a charter of incorporation. The Council received its present status under the direction of a Ministerial Committee of the Privy Council; hence the annual reports are formally presented "To the Lords of the Committee of the Privy Council for Medical Research." Looking back over the early years we may recall how much development was affected by the war, which broke out shortly after the work began. The success that attended the application of the principles and methods of scientific medicine to the medical war problems of 1914-19 had a great effect at that time. Appreciation of the importance of science to industry had been growing steadily, though very slowly, in Great Britain before 1914, and it was hoped that lessons taught to the public during the war would not be forgotten when the emergency organization for medical research was dissolved. At the breaking up of that organization many men marked by distinguished scientific achievement in the war were in danger of returning either to non-scientific duties or to teaching posts so poorly paid that they would have to augment their stipends by doing professional work of a kind incompatible with serious effort in research. Both public subvention and private munificence came to the rescue. The House of Commons made further financial provision for the universities (now administered through the University Grants Committee); it increased the annual vote for the Medical Research Council, and voted other money for scientific, industrial, and agricultural inquiries. The action of Parliament and the growth of public opinion stimulated benefactors to give or leave money to supply the needs of scientific research, and notably those of medical research, and this change of attitude made the lay authorities of many hospitals newly alive to their responsibilities for aiding the advancement of knowledge.

The Medical Research Council, whose report for the year 1936-7 appears this week (see p. 625), has acted throughout in co-operation with the universities and the medical schools attached to universities. The work done directly for the Council, or with its aid, includes that of the M.R.C. staff, whether in its own laboratories at the National Institute for Medical Research, in the clinical units it has established in various hospitals, or elsewhere. The record for the year also includes numerous researches, which are helped by grants from the Council, in the universities, hospitals, and other institutions in various parts of the country. Brief reference was made last year to the Government's intention to provide an additional sum of £30,000 per annum for the work of the Medical Research Council, with a special view to fostering progress in chemotherapy. This decision followed proposals framed by the Council in consultation with the Department of Scientific and Industrial Research, not only from the point of view of medical science but also with regard to industrial opportunity and national and colonial requirements. Chemotherapy, by definition, consists in the giving of chemical agents synthesized in the laboratory and found to have specific inhibitory actions on infective organisms causing particular diseases in man and animals. In a closely allied but much wider field of therapeutics advance depends on the same kind of investigation made by chemists and biologists working in collaboration. This wider field of research includes the discovery of chemical substances produced in the laboratory which have specific actions on certain bodily functions and which are thus of great value in the systematic treatment of disease as well as in other aspects of medical practice.

In so far as the chief role of chemotherapy has until recent months been in diseases of man and animals in tropical countries the subject is of peculiar importance to the British Empire. Yet the discovery and production of chemical compounds of value in this way has depended almost wholly on German science and industry, and still so depends. The outstanding exception (trypan-blue, for sleeping sickness) is of American origin; and the best example of a natural product for like purposes (quinine, for malaria) is practically a Dutch monopoly. Thus the needs of the British Empire for these drugs have to be met almost entirely from foreign sources. This is all the more remarkable and regrettable because several basic discoveries, opening up new fields in chemotherapy, have been made by British chemists and physiologists. From every point of view there is need for further research in Great Britain aimed at the discovery of new chemical substances of therapeutic

unconnected with childbirth, the most spectacular being streptococcal meningitis. The sulphanilamide compounds have been shown to have curative effects in infections by typhoid and other coliform bacteria, and, somewhat less impressively, in infections by pneumococci and staphylococci. From the standpoint of public health perhaps the greatest importance attaches to reports of curative effects of sulphanilamide compounds in acute and chronic gonorrhoea in both sexes. Some of these reports, however, are unfavourable, and it is thought well to suspend judgment for the present as to the complete efficacy of the treatment, though the reports may have arisen only owing to wrong dosage and administration. The indiscriminate sale of a preparation of this kind in America has had most unfortunate results, simply owing to the fact that another and quite unsuitable component had been added to the sulphanilamide itself. But it is necessary to warn the public that a powerful remedy must be used with discrimination and always under medical advice.

Among the various pieces of work narrated are some experimental studies of these compounds at Glasgow University, where the powerful curative effects of the drugs in mice infected with different strains of haemolytic streptococci, provided that the treatment is begun soon after infection, have been confirmed. No striking prophylactic effect against the streptococci was, however, demonstrable, and it has occasionally happened that mice, apparently cured of the infection, have developed fatal relapses after treatment has ceased.

The reason why progress has been so rapid in this field during the last year or so is easily explained. It is because, unlike the earlier attack upon protozoal parasites, this latest work has been concerned with organisms which can be easily seen and cultivated and which lend themselves to experimental investigation.

Immunology and Biological Standards

Some work at the National Institute carried out mainly during the year under review has opened up what may prove to be an important chapter in immunology. The production of passive immunity by injection of an antibody prepared in an animal of a different species has been familiar since the introduction of antitoxins for the treatment of diphtheria and the prevention of tetanus, but this interspecific type of immunity was of short duration. In some recent investigations on the nature of the substances neutralizing certain hormones a new type of interspecific has made its appearance. This substance appears in the blood serum of animals subjected to long-continued courses of injections of these hormones, and the evidence so far obtained suggests that it is of true antibody type.

Arising out of this work it has been found that diphtheria antitoxins from the horse, the goat, and the ox fail to cause any perceptible sensitiveness of the guinea-pig or its plain muscle to diphtheria toxoid, but that the antitoxin from a rabbit, and still more readily that prepared in a guinea-pig, render the guinea-pig and its isolated plain muscle highly anaphylactic to the diphtheria oxid. It is found, further, that serum from a man who has been successfully immunized belongs to the group of the rabbit and the guinea-pig rather than to that of the ungulates in that it readily makes the guinea-pig anaphylactic to the diphtheria toxoid. By a suitable adjustment of conditions guinea-pigs can be made actively, as well as passively, anaphylactic to the diphtheria antigen. It is thought that this new factor in the relation between an organism and an antibody artificially introduced into it, depending on the species yielding the antibody, may prove

to have important bearings on immunological therapeutics.

A reference is made to the new insulins. It is pointed out that these preparations have presented fresh problems of control under the Therapeutic Substances Act. The zinc-protamine-insulin has been the subject of a good deal of work by British manufacturers, controlled by suitable tests imposed under that Act. Experiments are still in progress, and information is being exchanged between the National Institute for Medical Research in this country and the Toronto Insulin Committee with the object of further improving the tests which control the activity of this important preparation of insulin.

The Virus of Influenza

In the report of the Council last year certain investigations were described which had led to the preparation of a vaccine from the lungs of mice infected with the influenza virus. This vaccine consisted of a filtrate from the infective material, inactivated by treatment with formaldehyde. The widespread epidemic of influenza in the winter of 1936-7 gave an opportunity for observations and trials of the virus, and the high percentage of positive results has strongly reinforced the identification of the virus as the primary cause of the infection, especially when contrasted with the uniform failure to obtain the virus from non-influenzal cases of respiratory infection. From a detailed clinical study of influenza as seen in 120 patients—chiefly in Service hospitals—it is tentatively concluded that the disease caused in man by infection with the influenza virus probably constitutes a recognizable clinical entity, differing in symptoms as well as in its epidemiological character from other catarrhal infections of the respiratory tract which have often been confused with it.

The misuse of the term "influenza" as a label for various catarrhal conditions is therefore all the more to be deprecated. The misuse arose inevitably at a time when the causative organism of influenza was unknown, and probably it continues by reason of a preference on the part of patients to describe their ailment as influenza, which is considered an adequate reason for invalidism, whereas "catarrh" is not.

The results of vaccination against influenza have so far been inconclusive. Vaccination with the inactivated virus does not give protection in all cases, even when the conditions are favourable. All that can be said at present is that if vaccination is to have a good chance of success in any future epidemic it will be necessary to choose an inoculum made from a virus belonging to the same immunological group as that responsible for the immediate outbreak.

A note is appended to the report on a method of egg-membrane culture in the study of viruses, including that of influenza. It has been found that a number of viruses can be propagated in the developing egg of the domestic fowl, and such eggs can now be used with advantage to replace experimental animals. This laboratory method is likely to prove its utility in the study of diseases due to infection with filter-passing viruses.

(To be concluded)

A new hospital at Cape Town has been opened by the Governor-General, Sir Patrick Duncan. This building consists of five floors, and there are 850 beds, of which seventy-seven are for paying patients. According to Reuter, it is the best-equipped hospital in the Union of South Africa, and has cost approximately £1,000,000.

been performed; interns have absented themselves from duty without permission and even against orders. It is an all too common occurrence for interns to pack up and leave whenever a likely opening in practice presents itself." Further, the conditions of licensure in the Dominion and in its several Provinces differ from those in Great Britain. Whereas here the possession of a recognized diploma or degree of itself entitles the entry of a name on the *Medical Register*, in Canada further examinational tests and requirements have to be fulfilled before the licence to practise is granted. Such differences may increase or lessen the difficulties to be overcome if either undergraduate or immediate postgraduate internship (or some corresponding alternative) is to be made a condition of entry upon independent practice; but they do not in any degree detract from the mutual obligations of the intern and those under whose supervision and responsibility he acts.

The statement and clarification of these obligations are the main concern of this joint report. The purpose of internship is described succinctly and admirably, and under no fewer than twenty-six headings there are set out what should be the conditions and procedure of intern education. The main desiderata are a definite programme of instruction; adequate facilities for work and discussion of cases; increasing familiarity with nursing procedures, the administrative problems of hospitals, the social aspects of medical care, and the requirements of medical ethics; responsibility in the out-patient department, and experience in dealing with patients in "private" wards; health supervision and recreative activities; and, as absolutely vital, a real interest in the welfare and education of interns on the part of the medical staff, both individually and collectively. Most of the points are developed in some detail, and it is much to be hoped that this valuable report may be made the basis of discussions, leading to practical improvements in medical education, both in the immediate and in the more remote future.

SERUM TREATMENT IN GONORRHOEA

We published last year an account¹ by T. Anwyl Davies of the results of treating gonorrhoea with "gonococcus antitoxin." This account was exceedingly favourable; the serum had a clearly specific effect, the duration of the disease being lowered while complications were reduced in frequency or responded remarkably to the treatment. In subsequent correspondence the significance of these observations was questioned, mainly on the grounds that they were uncontrolled by comparison with other cases not treated with serum, and that the

possible effect of other measures had not been taken into account. In spite of these elements of doubt the enthusiastic nature of this report induced E. T. Burke, J. Gabe, A. H. Harkness, and A. J. King to adopt the treatment in three venereal clinics, and a combined account of their experiences appears in our opening pages to-day. This account is wholly unfavourable; the serum had no specific anti-gonococcal effect; recovery, so far from being accelerated, was interfered with, and serious reactions were frequently produced. There can rarely have been a flatter contradiction between the results of two series of observations on similar patients and with the same remedy. Careful analysis of the records on both sides would doubtless reveal minor differences in procedure, but it seems altogether unlikely that unrecorded variations of this kind could explain so glaring a discrepancy. Therapeutic trial must always be the final court of appeal in assessing the merits of any remedy, but let us admit that its judgments are fallible. There are other grounds upon which the claims of "gonococcus antitoxin" to be a specific remedy may be judged, and to these we referred in editorial comment² on Dr. Anwyl Davies's paper. The supposition involved in the mode of preparation of this serum, that the gonococcus produces an exotoxin, is disputed, and the methods available for testing such a serum have unfortunately little claim to significance as an index of therapeutic value. There was therefore no strong *prima facie* case in favour of this serum, and a favourable verdict on it had to rest on those reported results of clinical trial which now meet so emphatic a denial. It was pointed out in the correspondence of last year that further research in methods of serum preparation was needed, and although this remains generally true, it may be doubted whether any such efforts are now likely to take gonorrhoea as one of their earlier objectives, or indeed perhaps meningococcal meningitis, which is also involved in the same difficulty. During the past year the new chemotherapy has widened its scope to include both these diseases, and in both it seems capable of achieving at least as much as serum ever has; in gonorrhoea certainly more, according to many recent reports.

ENCEPHALITIZOIC ENCEPHALOMYELITIS

Little is known of intra-uterine infections apart from syphilis, and so fresh ground is broken by A. Wolf and D. Cowen³ in their recent description of an undoubted example of an encephalomyelitis of this kind due to an organism resembling the *Encephalitozoon cuniculi*—a parasite causing spontaneous encephalitis in rabbits and mice. In retrospect the authors surmise that two similar cases have already been reported in the literature, but these are insufficiently documented to establish this point. The case now reported was in an infant which came under medical observation at the age of 24 days suffering from convulsions. It was born of parents who had spent their lives in or near New York City and were apparently healthy. During the first five

value, and strong reason for developing a national scheme of investigation. An outline of research work on chemotherapy proceeding in this country under the auspices of the Council is given in the present report, with proposals for further development, more especially in the highly important direction of the treatment of streptococcal and certain other bacterial infections with sulphanilamide and allied substances.¹

Other matters discussed at some length in the general introduction are influenza, surgery of the heart, the causes of mental defect, the role of common salt in the body, and the part played by nicotinic acid in biological phenomena with special reference to its action as a vitamin of the B complex. As in former years, the work of the National Institute for Medical Research, under the direction of Sir Henry Dale, is set out in some detail. The need for additional laboratories for the new work on chemotherapy is one of several factors which have raised in acute form the question of future policy regarding the site and buildings of the National Institute. After long consideration of the problem in all its bearings the Council has decided in principle to abandon the Mount Vernon site at Hampstead and to concentrate the whole of the National Institute at Mill Hill. The main advantage of this will be the close contact and means for collaboration between different departments and the convenience of common services, with greater ease of control and economy in maintenance. Proximity to the new laboratories of the Imperial Cancer Research Fund at Mill Hill on land leased by the Council will bring mutual benefit.

The success of the policy followed from its early beginnings by the Medical Research Council is not often questioned to-day, and few would now deny the debt owed by British medicine to the zeal and foresight and good judgment of Sir Walter Fletcher, who left his physiological work in Cambridge to accept the arduous duties of secretary of the new body. The tradition set by Fletcher has been continued since his death by Sir Edward Mellanby. Both secretaries have been fortunate in their chairmen and in their office colleague, Dr. Landsborough Thomson.

INTERNSHIP AND MEDICAL EDUCATION

One of the most important suggestions made by the British Medical Association's Committee on Medical Education in its report of July, 1934, was that each student should be given, within the period of the curriculum, not less than six months' responsible clinical experience under supervision,

together with instruction in certain aspects of medical practice. The conditions under which, and the methods by which, such experience, supervision, and instruction should be secured were laid down with some particularity. It was recognized, however, that there would be much difficulty in giving immediate practical effect to these proposals; and eventually, while reiterating the conviction of their great value, the Association was content to express the hope and belief that further consideration will lead to their adoption when the curriculum is next under revision by the General Medical Council, presumably some years hence. That those concerned with medical education in Canada (and incidentally in the United States of America too) are now coming to similar conclusions is evidenced by a report on "Intern Education and Supervision," prepared by a joint committee of the Ontario Medical Association and the Canadian Medical Association.¹ This report is a really important study of its subject, and though it deals with the matter mainly from the aspect of hospital service—the duty of the intern to the hospital and of the hospital to the intern—it includes the consideration of such questions as undergraduate internship, resident posts in specialties, the legal status of interns and of students in a like position prior to licence to practise, the alternative plan of a period of practice in conjunction with a senior private practitioner, and the issue of a temporary interim certificate to practise in these and similar circumstances. Some of these points require further study and elaboration, but it is noteworthy that they have been brought definitely into the field of serious discussion and that there is an apparently widespread feeling that they embody a policy or a cause which is in itself desirable, and the difficulties of which, though evident, should be faced and overcome.

The position on the other side of the Atlantic is not identical with that in Great Britain and Ireland. In Canada it appears that the number of openings for internship is much in excess of the number of students available to fill them, whereas on this side it would require some organization and much co-operation between various types of hospital to provide a large enough number of resident posts. Again, Canada complains of a laxity in observing contractual obligations in this sphere which is rarely, if ever, seen in this country. It is astonishing to read that among certain interns—though the offenders constitute only a minority—"long alternate week-ends are being demanded without consideration of the needs of the patients; strikes have occurred for higher pay; assigned duties have not

receiving additional vitamin B. The percentage of babies showing anorexia was about the same in both groups. Thus with the exception of the promotion of a more stabilized growth and what is termed "greater nutritional stability" there was no obvious advantage in adding vitamin B to the diet of healthy, well-managed infants. Certain psychometric observations were also undertaken.² The general picture of the infants receiving increased amounts of vitamin B is summarized as "one of slightly accelerated maturation in basic behaviour patterns (except the sympathetic), augmented alertness in attention and perception phenomena, and slightly accelerated adaptive behaviour patterns (learning)." On the other hand there were many individual variations, and, in fact, with certain types of co-ordination there was an actual lack among the babies receiving extra vitamin B at the age of 1 year. Much time and energy have obviously been expended on these investigations, and if the more or less negative results obtained are accepted as final it would appear that no supplements of vitamin B to children's diets are really necessary.

THE HOSPITALS OF CORNWALL

It is probable that the report of the Voluntary Hospitals Commission issued last year carried conviction that some scheme for the grouping of hospitals in areas or regions was highly desirable or even necessary. To translate conviction into action may be much more difficult. It is therefore a good thing that a further committee should have been set up with a view to implementing the recommendations of that report, and that some survey of county areas in England and Wales should have been taken in hand. One such survey of the hospitals in Cornwall has just been issued. It was made by Dr. Eric Donaldson, representing the Ministry of Health, and Mr. R. H. P. Orde, the honorary secretary of the British Hospitals Association, in response to a resolution passed last August at a meeting of representatives of the voluntary hospitals of the county at Truro inviting such a joint survey. In due course a meeting of the hospital representatives is to be called to consider this joint report. Conditions in Cornwall are in some respects unique among those of the English counties. Truro is the capital town and is fairly centrally situated, but there are three or four other towns in the county of approximately the same size, and none of them is large. In both Truro and Redruth there are at present hospitals the enlargement of which is in progress or in contemplation, and these towns are within eleven miles of each other. The other hospitals of the county are small, but the total accommodation seems to be sufficient; and the Penzance hospital is the only one which shows some signs of overcrowding. There are four small hospitals in East Cornwall whose natural outlook is towards Plymouth rather than towards Truro—Stratton, Liskeard, Saltash, and Launceston—so that in this case, as probably in most other counties, the actual county area does not constitute the most convenient hospital region. The joint report suggests

that these four hospitals shall continue to be based upon the Prince of Wales's Hospital at Plymouth as their central hospital, and that the other smaller hospitals of the rest of Cornwall shall be based upon the combined Truro and Redruth hospitals. These two, it is recommended, should combine at least so far as to share the same staff of physicians, surgeons, and specialists, and to develop those special departments which they already possess. The Royal Cornwall Infirmary at Truro would develop as the orthopaedic centre, establish a fracture clinic, and also throat, nose, and ear and ophthalmic departments, while the West Cornwall Miners' and Women's Hospital at Redruth would become the maternity centre and an outlying radiological centre linked with the national radium centre at Plymouth. In both would be treated general medical and surgical patients.

THE CASH BASIS FOR PROFESSIONAL ACCOUNTS

Recent correspondence in the columns of a technical periodical—*Taxation*—suggests that some misapprehension still exists as to the precise nature of the cash basis, and particularly as to the result of a change of proprietorship, in whole or in part, on the income-tax liability of those concerned. The point around which discussion often ranges is whether the vendor of a practice should account for income tax on the cash received by him after the date of sale, or, as it was put in a letter published by the journal referred to above, "What law prevents the Revenue (seeing they will not have another chance) from including the outstanding debts in that adjusted assessment, less, of course, an allowance, based on experience, for bad debts?" The writer proceeds to answer the question by adding: "I don't see how such an assessment could be resisted." With all respect we differ from his conclusion. The matter is one which has created discussion and misunderstanding for many years, but in essence is fairly simple. The professional profit of any particular year is the excess of the year's earnings over the year's expenses. Where credit is given the earnings of the first year—that is, the value to the practitioner of the consideration given or to be given for the services rendered—will clearly be less than the cash he will receive in the same year. There will be a "lag" in his cash receipts represented by, say, £x. But the Revenue authorities will rightly require him to include that sum in his gross earnings. At the end of his second year he may have received the £x, but another "lag" has been set up of, say, £y, and he will have to add to his cash receipts for the second year an amount represented by the excess of £y over £x. After, say, three years, however, it is probable that the cash receipts from work for previous years will be about equal to the uncollected debts arising out of the work of the year under consideration; the "lag" will have vanished, the cash receipts will have become a reasonably reliable measure of the year's earnings and the most convenient way of arriving at the profit. That is recognized by

² *Amer. J. Dis. Child.*, 1937, 54, 750.

months of the pregnancy they had lived in an apartment which was heavily infested with mice; there had been no contact with rabbits. Two days after birth the infant began to have convulsions, followed by diarrhoea and vomiting. It was acutely ill when admitted to hospital, with bulging fontanelle and slight head retraction. Xanthochromic fluid containing an excess of mononuclear cells and protein was withdrawn by lumbar and ventricular puncture. No growth was obtained on aerobic and anaerobic culture of these fluids. Both retinæ showed patches of yellowish-white inflammatory exudate. The infant died after five days in hospital. The necropsy, which was performed three hours later, revealed nothing of outstanding interest, apart from the central nervous system. This showed, to the naked eye, focal exudative meningitis with patchy areas of discoloration and necrosis in the underlying brain. The ventricles were dilated and their ependymal lining was replaced by stringy exudate and raised islands of yellowish tissue. The basal ganglia were friable and showed patches of yellowish discoloration. Microscopically the whole central nervous system was unequally affected by a meningo-encephalitis, which proceeded in places to necrosis and caseation and, in less severely inflamed areas, to the formation of discrete miliary granulomas. The latter were most frequently found in the white matter, the tissue in the neighbourhood of the lateral ventricles being severely affected. The spinal cord and the brain-stem were less involved than the cerebral hemispheres. Especially noteworthy are the changes described in the optic nerves and retinæ, where similar granulomatous lesions were present. A careful examination of the fundi is therefore indicated in the investigation of any future patients who may be thought to fall within this class of case. The organisms found in the lesions are fully and carefully described and are illustrated by photomicrographs and a colour plate. They closely resemble the *Encephalitozoon cuniculi*, and, as the authors point out, the lesions which this organism can produce in the rabbit and mouse are of a similar histological character. Its life cycle is unknown, and hence the means whereby human beings may become infected is at present obscure.

PHYSICIANS OF THE MAYO CLINIC

A distinguished editor once said that whenever he had nightmare his dream always took the form that Mr. Gladstone had died suddenly just after the paper had gone to press and that the stock obituary had been inadvertently destroyed. *Physicians and Surgeons of the Mayo Clinic and Mayo Foundation*¹ will save future editors from a similar nightmare as regards the alumni of that great school, and they alone will be able to appreciate its full value. The book consists of short biographies arranged alphabetically, each with a portrait and a hand-list—improperly called a bibliography—of the alumni of Rochester. The major part of the work is devoted to those who have been officially connected with the Clinic or Foundation for a year or more. A

second and smaller section tells of those who have served for a shorter time. There are appendices giving the universities at which the alumni were educated and the countries and States where they were born. The record fills 1,571 octavo pages and shows the world-wide influence which the Rochester school has exercised upon the progress of surgery. The book is issued in the U.S.A. by the University of Minnesota Press and in Great Britain by the Oxford University Press. The editorial duties have fallen upon Dr. and Mrs. R. M. Hewitt, who have carried out the work with the able help of members of the Division of Publications of the Mayo Clinic.

PROBLEMS OF VITAMIN B DEFICIENCY

Although gross lack of vitamin B is met with rarely in this country and in the U.S.A., moderate deficiency is perhaps not uncommon. A suboptimal intake of vitamin B is said to lead to such ill-defined functional disorders as anorexia, inefficient utilization of food, and a lowered haemoglobin content. Many of the investigations have been conducted on children living in institutions or presumably under-nourished before the special additions of vitamin B have been made. M. W. Poole and his co-workers have now published¹ an important study on the effect of adding vitamin B to the usual diet of healthy infants. Great care was taken to secure, so far as possible, comparable groups of "average well" babies, of whom two-thirds were white and one-third negro. The children were attending a special clinic for observation, but otherwise they were left in their own homes and cared for by their own parents. A special evaporated milk was used throughout the experiment, and apparently contained about 227 Sherman-Chase units of vitamin B in the average daily quantity of milk taken. One group of babies was taken as a control, and another group, numbering seventy-four, received a diet to which specially prepared extracts of rice polishings were added, giving the average daily content of 320 Sherman-Chase units of vitamin B. In all other respects the diets were kept as nearly identical as possible, and the amounts of cod-liver oil and vitamin C added were carefully watched. The main result of the experiment was negative. The babies in the control group gained in weight and in length approximately as well as those receiving extra vitamin B, but there was a definite smoothing of the weight curves, and the average gain was more regular and consistent, among those receiving extra vitamin B. From the detailed observations made it seems clear that the supplement of vitamin B had a mild laxative effect, for twice as many cases of mild diarrhoea were observed among the infants receiving the increased amount: on the other hand, constipation, which was uncommon, occurred with equal frequency in the two groups. There was no difference in dentition in the two groups, and in the matter of resistance to infection it was observed that when all grades of severity of nasopharyngitis were added to bronchitis and pneumonia the number of "infections per infant" was slightly higher in the group

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

FOREIGN BODIES IN THE TISSUES

BY

HAROLD DODD, M.Ch., F.R.C.S.

The removal of foreign bodies from the tissues can be a humiliating and a time-consuming experience, but a preliminary study and preparation will eliminate much of the usual difficulty. Foreign bodies in the eye and the respiratory, alimentary, and urinary tracts are not dealt with in this article, nor are wartime missiles.

In general practice and hospital service three types of foreign body are commonly met with: (1) hypodermic needles in the arm and buttock; (2) domestic needles and pins in the hands and feet; (3) miscellaneous substances—glass, wooden splinters, shot, metal filings, pieces of clothing, etc.

Hypodermic Needles

Treatment with insulin at home and the large amount of injection therapy now given result fairly often in hypodermic needles being broken in the tissues. Apart from the surgical aspect a medico-legal point is raised, and a working rule can be laid down that even though the needle fragment is in a situation where it is apparently innocuous the patient or his guardian must always be informed, a radiograph taken, and removal advised. If intervention is thought to be of doubtful value, then a consultation with a colleague should be sought and a considered opinion expressed, thus safeguarding both patient and practitioner.

An embedded hypodermic needle may exert a bad effect on the patient's health, as the following case illustrates:

A diabetic girl aged 20 was given insulin twice a day by her mother; she took a generous diet and kept sugar-free. One day a hypodermic needle broke in her arm, and after this, although more insulin was given and the diet was reduced, the glycosuria returned. She was admitted to hospital, where the needle was located by radiographs, but its extraction was deferred until the urine was sugar-free, owing to the possible danger of spreading infection in the wound. After a month's treatment the sugar persisted, and the opinion was formed that there was low-grade sepsis about the needle which exerted a toxic effect on the islets of Langerhans; consequently the needle was removed. There was a bead of pus around it, although no external signs of inflammation were visible. The next day the patient was sugar-free and has remained so.

It is common knowledge that hypodermic needles almost invariably break at the same place—that is, the junction of the shaft with the syringe piece, where the old-type plated needles of carbon steel corrode; the newer stainless needles, which bend rather than fracture, are better. Before giving an injection the point of the needle should always be inspected and tested, and from time to time it will be found broken off or bent over; a blunt needle has indifferent penetrating power.

Domestic Sewing Needles

Domestic sewing needles are a more difficult problem. They often penetrate deeply, perhaps between the metacarpals or metatarsals; besides which, some patients delay seeking treatment until the point of entry has healed and cannot be seen. Stories of a fortuitous spontaneous evacuation some distance away from the original wound are common, but such occurrences are exceptional.

Treatment

It is a *sine qua non* that all parts containing foreign bodies, suspect or actual, must be radiographed in two or more planes before removal is attempted. Stereoscopic films are a further assistance. Unfortunately, not all articles are opaque to x rays, but it is surprising what an amount of detail a good film will show.

Objects buried in the tissues should never be removed without: (1) access to an operating theatre or an x-ray table arranged as an operation table; (2) a good light; (3) preliminary radiographs in two or three planes, or a portable x-ray apparatus; (4) plenty of time; (5) an anaesthetic—local infiltration, spinal, or general; (6) when possible, exsanguination of the part by a tourniquet; (7) the patient being admitted to hospital or a nursing home.

The incision should be planned with due regard to the anatomical structures—for example, avoiding nerves, tendons, and arteries. An approach transverse to the axis of the needle must surely strike it, and should be used when permissible. The x-ray film is but a shadow: film distances and sizes are misleading, and must be estimated in relation to palpable bony points rather than by measurement on the negative. Thus "one inch below the radial styloid" will not be satisfactory, but a proportion of the distance between the ulnar and radial styloids—for example, a half or a third—is likely to be less erroneous. Further precise assistance is available from one of the following methods, modified according to the individual problem.

A long straight cutting needle is inserted into the part, aimed to strike the middle of the foreign body. Then a second needle at right angles to the first is similarly introduced. Lloyd (1936), writing on foreign bodies about the tarsals and metatarsals, advises the use of a Kirschner wire in the same manner, whilst a further aid to orientation is the insertion of a Michel's clip or clips into the skin. X-ray films in two positions are then taken, and from them the surgeon estimates the lie of the foreign body and plans the incision accordingly. If the guide needles are wide of the mark they are reinserted, or additional ones are used and more films are taken. The time spent in this preliminary investigation obviates tedious fumbling operations, with possible injury to important structures; in fact, the actual extraction often proves to be easy.

Harris (1936) describes a practical point that assists in the location of a recently entered foreign body. He states that as the needle penetrates it makes a track of ruptured capillaries and contused tissue, with a small extravasation of blood, and that if the part is completely exsanguinated this track remains red, brown, etc. (according to its age), and is clearly visible. It is traceable for several weeks after the accident. The limb is elevated for five minutes and an Esmarch bandage is applied. The position of the needle is estimated from the history and the radiograph, and the incision passes through the exact or an approximate point of entry. The dark red track, now easily identified in the white glistening tissue, is carefully followed to the foreign body. The method is applicable only to bodies in the upper and lower limbs, not for the buttocks. Caution in the use of a tourniquet on the arm and forearm is always necessary, for a median or ulnar palsy is rapidly caused; good padding and the minimum

the income-tax authorities, and is the basis on which most medical returns are made and accepted. Let us now look at the "final" year—that is, the year immediately prior to the sale of the practice by A. to B. A.'s cash receipts in that year are, we will suppose, £2,000, and he expects to receive a further £500 as the outstanding debts are collected. There seem to be very firm grounds on which A. could resist an assessment based on regarding his gross earnings for the final year as £2,500. In the first place that amount is clearly £500 too much: all the facts indicate gross earnings of £2,000 only in one year; secondly, the £500 represents A.'s compensation for having accounted for tax in his first three or four years on sums in excess of his cash receipts for that year. The Revenue cannot have it both ways; they cannot put the cash basis aside when the result is inadequate and adhere to it when it is excessive—and to do them justice they do not desire to do so. We have stated the simplest case—that of a sale of a single-handed practice—but the same principle applies where the change in proprietorship operates through a change in the constitution of a partnership—that is, the outgoing partner should not be required to account for tax on cash received by him after the date from which the change takes effect. Where, however, a partnership is concerned the question is one which usually affects the partners only, the amount of tax payable not being materially affected, and in such circumstances the precise terms of the agreement entered into by the partners will of course govern the matter so far as they are concerned.

MEDICAL WORK IN THE SUDAN

The report of the Sudan Medical Service for 1936 reflects the greatest credit on the Director and his staff. It is a mine of interesting information, and every item is readily accessible. When it is recalled that there are only forty-three British medical officers in the Sudan Medical Service, and that the country, though sparsely populated, is vast in extent, the quality, quantity, and diversity of work performed, as described in the report, compel the reader's admiration. A wise delegation of authority to native officials is the keynote of the administration. In addition to fifty-two Sudanese medical officers, trained at the Kitchener School of Medicine, Khartoum, there are 239 Sudanese assistant medical officers. These latter are selected after several years' training as hospital orderlies. They first undergo a year's special course, followed by an examination. They are then placed in charge of dispensaries. A network of these dispensaries, 337 in number, covers the whole country, and thus brings medical aid within reasonable reach of the entire population.

"The establishment of an adequate hospital and dispensary service is the first task in the medical administration of a country, as it enables the confidence of the people to be gained, and sweetens the pill of preventive medicine which follows it; but it is essential that the progress of the second and really more important function of a medical service, that of prevention of disease, is not held back by lack of funds owing to the cost of the more popular and spectacular curative branch."
